Atmospheric Apparatus for Ultra-Violet Light Therapy

THESE are ideal lamps for, not only the general practitioner, but also for hospitals and clinics. In this new design the cowl is arranged for general irradiation and for local treatment by means of the usual applicators. The lamp standard admits of universal movement of cowl, which is mounted on counter-balanced cross-arm.

Emol-Keleet

The Natural Sedative
Emollient
DUSTING POWDER.
Impalpable, Inorganic, Absorbent.

In Skin Affections—

During the eruptive and irritating stages of Measles and Scarlet Fever, and following Vaccination, marked relief is afforded by applications of Emol-Keleet. Purulent Eczema and Inflammatory Papulæ, too, are greatly ameliorated by its sedative and absorbent action.

Samples free to the Medical Profession on request.

FASSETT & JOHNSON, LTD., 86, Clerkenwell Road, London, E.C.1.

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World.

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2

NATIONAL SUN-RAY
AND HEALTH CENTRES LTD.,
845/850, SALISBURY HOUSE, LONDON WALL, E.C.2.

The Board of Directors of the above Company desire to make known to the Medical Profession their decision to cease all advertisements to the Lay Public and to conduct their Centres in strict accordance with the recognised principles of the Medical Profession.

Each of their Centres will be under the control of whole-time qualified, registered medical practitioners, assisted by a staff of trained male and female operators.

The Directors desire medical practitioners to realise that they may refer such of their patients as, in their opinion, are likely to benefit by Actino-therapy and other Physio-therapeutic measures, to these Centres with every confidence.

The Medical Officer at each Centre will at all times be pleased to see any local practitioners who may wish to satisfy themselves as to the nature of the provision made for their patients' treatment and comfort.

Interested Practitioners should write to the Head Office for Literature, or to the Ealing Treatment Centre, 23a, The Broadway, Ealing, London, W.5. Telephone: Ealing 2843.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel: Langham 1160.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) CH.M.EDINBURGH. M.C.CANTAB.
F.R.C.S.EDINBURGH. M.S.LONDON.
And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S.," free on application to the Secretary.

Apply, Dr. SAVAGE, County Health Department, Weston-super-Mare.

Parish of Stepney.

The Guardians invite applications from duly qualified registered medical practitioners who are prepared to act as PART-TIME CONSULTANT SPECIALISTS in the following branches of Medicine *and* Surgery, at the Guardians' three hospitals—viz., MILE END HOSPITAL, Bancroft road, London, E.1, ST. PETER'S (WHITECHAPEL) HOSPITAL, Vallance Road, London, E.1, and ST. GEORGE-IN-THE-EAST HOSPITAL, Raine Street, Wapping, London, E.1:

CONSULTANT SURGEON (to attend once a fortnight at each hospital. Remuneration at the rate of £350 per annum).

CONSULTANT PHYSICIAN (to attend once a fortnight at each Hospital. Remuneration at the rate of £200 per annum)

CONSULTANT SURGEON for Ear, Nose, and Throat (to attend once per week at the Mile End Hospital. Remuneration at the rate of £150 per annum).

CONSULTANT OPHTHALMIC SURGEON (to attend two sessions per week at St. Peter's (Whitechapel) Hospital. Remuneration at the rate of £200 per annum).

The Guardians require that the Specialists appointed will attend at definite agreed times during each of the sessions above referred to, and will undertake also to attend at other times, *when specially called upon.*

All candidates must be at present Surgeons (or Assistant Surgeons) or Physicians (or Assistant Physicians) as the case may be, on the staff of a general Hospital in London. The appointments will be for a period of one year only, and the gentlemen appointed will be required to provide Deputies at their own expense in the case of inability to attend and during summer holidays.

Forms of application may be obtained at this *office, and must be returned to me by not later than March 9th.*

By Order,
Administrative Offices, Bancroft Rd., E.1. S. MCCLELLAND, Clerk to the Guardians.
February 14th, 1929.

County Council of Durham.

EDUCATION DEPARTMENT.

ASSISTANT OCULIST.

Applications are invited for the post of Assistant School Oculist to the Education Committee. Candidates must be skilled Refractionists, and must also have occupied the post of House Surgeon in an Eye Hospital or in the Eye Department of a General Hospital for a period of not less than six months. Commencing salary £600 per annum, rising by annual increments of £25 to a maximum of £650 per annum, with travelling expenses in accordance with the County Regulations

The person appointed will hold an established post under the Local Government and Other *Officers Superannuation Act, 1922*, and will be subject to the provisions of the Act. He will be required to devote his whole time to the duties of the office, and to reside at a place to be approved by the Education Committee. The appointment will be subject to three calendar months' notice on either side, expiring on the last day of any calendar month. Canvassing, directly or indirectly, is prohibited and will disqualify. Forms of application to be returned not later than Saturday, March 16th, can be obtained from the Director of Education, Shire Hall, Durham, *on* receipt of a stamped addressed envelope.

Shire Hall, Durham. A. J. DAWSON, Director of Education.
February 18th, 1929.

Metropolitan Asylums Board.

The Board invite applications for the appointment of SENIOR ASSISTANT MEDICAL OFFICER in their Mental Hospitals Service. Commencing salary £650, rising by £32 10s. per annum to £800 per annum. Candidates must be under 40 years of age, and must have had previous Mental Hospital experience.

Preference will be given to those holding the Diploma in Psychological Medicine.

Form of application may be obtained by sending stamped addressed foolscap envelope to the Clerk to the Board, Metropolitan Asylums Board, Victoria Embankment, E.C.4, to whom they should be returned not later than March 11th.

ALLAN POWELL,
Clerk to the Board.

Senior Resident Medical Officer

(lady, unmarried) wanted for the ISLINGTON DISPENSARY, 303, Upper St., N.1. Candidates must be Fellows or *Members of the* Royal College of Surgeons, and qualified to practise Medicine and Surgery. Salary £300 p.a., with apartments (*furnished*). *Applications*, before March 7th, on printed form to be obtained (by post-card) from the Hon. Secretary at the Dispensary. Duties begin at end of *March.*

EAST AFRICAN MEDICAL SERVICE

APPOINTMENTS

VACANCIES exist at present for MEDICAL OFFICERS and HEALTH OFFICERS in the EAST AFRICAN MEDICAL SERVICE.

Candidates should be British subjects of European parentage and not over 35 years of age. Preference will be given in the case of Medical Officers to candidates who have held House appointments as House Physicians and House Surgeons. In the case of Health Officers a Diploma in Public Health is essential. Candidates should apply, in writing, to the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, London, S.W.1, for the necessary forms of application.

SALARIES.

MEDICAL OFFICERS £600 per annum, rising by annual increments of £30 to £840 per annum, and thence, subject to an efficiency bar, by increments of £40 to £920 per annum.

HEALTH OFFICERS enter the scale at £660.

QUARTERS.

Free quarters are provided, or an allowance is given in lieu.

PASSAGES.

Free first-class passages are provided, both on first appointment and when proceeding on leave. A married officer will be granted an allowance towards the cost of his family's passage once each way in respect of each tour of service.

THE SUDAN GOVERNMENT.

A MEDICAL OFFICER is required for Public Health Duty for the Sudan Medical Service.

The candidate should be single, under 36 years of age, and he must have a D.P.H. degree.

Pay for the post commences at £E.852, rising by degrees to £E.1,200. On confirmation of the appointment, the accepted candidate will be eligible for Pension Service.

Applications (in writing only), with copies of recent testimonials, should be sent to Dr. HODSON, 24, Welbeck Street, W.1, from whom further particulars can be obtained.

Administrative County of Surrey

APPOINTMENT OF COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Surrey invite applications from duly qualified medical practitioners holding a Diploma of Public Health for the office of County Medical Officer of Health.

The person appointed will be required to act as Head of the County Medical Services and to perform any additional duties relating to Public Health which may be imposed upon the Council by new legislation.

The remuneration will be a net personal salary of £1,600 per annum.

The appointment is designated an established post under the Local Government and Other Officers Superannuation Act, 1922, and will be held subject to the provisions of that Act, to the Orders for the time being of the Minister of Health, and to the Standing Orders of the Council.

Applications on the prescribed form (which, with a general statement of the conditions and duties of the office, may be obtained from me on receipt of a stamped and addressed envelope), accompanied by copies of not more than three recent testimonials, must be sent in a sealed envelope marked "C.M.O.H.," to reach me at the undermentioned address not later than Thursday, February 28th.

Canvassing by or in favour of a candidate will disqualify the applicant.

County Hall, Kingston-upon-Thames. February 1st, 1929. DUDLEY AUKLAND, Clerk of the Council.

Derbyshire Education Committee

ASSISTANT SCHOOL MEDICAL OFFICER (MALE).

The Derbyshire Education Committee require the services of an Assistant School Medical Officer (male) at a salary of £600, rising by annual increments of £25 to £700 per annum.

The candidate must be a registered Medical Practitioner of at least three years' standing. Experience in Refraction, Mental Deficiency, and Anæsthetic Work will be considered additional qualifications.

The officer appointed will not be allowed to engage in private or consulting practice, but will be required to devote his whole time to the duties of the office, and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before March 11th, endorsed "Assistant School Medical Officer."

The appointment will be determinable by three months' notice on either side.

New County Offices, St. Mary's Gate, Derby, February 16th, 1929. W. M. ASH, School Medical Officer.

West Derby Union.

RESIDENT ASSISTANT MEDICAL OFFICER (Male).

The Guardians invite applications for the above position at the MILL ROAD INFIRMARY, EVERTON, LIVERPOOL, at a salary after the rate of £200 per annum, together with rations, apartments, etc.

Candidates must be single, fully qualified, and registered.

Other things being equal, preference will be given to local candidates.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, 1896.

Appointment will be for a period of one year in the first instance, subject to one month's notice to terminate on either side at any time, and to extension for a further period of twelve months at the option of the Guardians.

Applications to be sent, stating age, qualifications, etc., with copies of three recent testimonials, to the undersigned not later than first post on Monday, March 4th.

Union Offices, Brougham Terrace, Liverpool. February 18th, 1929. G. O. HOLLOWAY, Clerk to the Guardians.

British Red Cross Society's

CLINIC FOR TREATMENT OF RHEUMATIC DISEASES.

A Clinic for the treatment of Rheumatic Diseases will be opened in Park Square, Regent's Park, N.W.1, in the Autumn of the present year.

The British Red Cross Society Committee of the above will shortly proceed to appoint SIX MEMBERS OF THE HONORARY VISITING MEDICAL STAFF, each of whom will be required, when the Clinic is in full working order, to attend twice a week. Application, in the first place by letter only, should be addressed, on or before March 1st, 1929, to the Secretary of the Clinic Committee, British Red Cross Society, 19, Berkeley Street, London, W.1.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of a Male Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the medical inspection of school children, maternity and child welfare, and the treatment of tuberculous and venereal diseases. The officer appointed will be required to undertake such other public health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, 5, Grove Crescent, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day for receipt of applications, Thursday, February 28th. Canvassing, directly or indirectly, will disqualify.

County Hall, Kingston-upon-Thames. Feb. 12th, 1929. DUDLEY AUKLAND, Clerk of the County Council.

[AMENDED ADVERTISEMENT]

Rochford Hospital.

MALE ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the appointment of Male Assistant Resident Medical Officer at the Hospital, Rochford, near Southend-on-Sea.

The appointment will, in the first instance, be for twelve months, with salary at the rate of £300 per annum. If the officer is re-appointed after twelve months' service the salary will be increased to £350 per annum. In addition, arrangements will be made for the officer to be provided with apartments, laundry, and maintenance outside of the Hospital to the limit of £200 per annum. The salary and value of emoluments are subject to deductions under the Poor Law Officers Superannuation Act, 1896.

Applicants must be fully qualified, and must have had at least two years' resident Hospital experience. He will be required to take charge of the Hospital during the absence of the Resident Medical Officer.

The Rochford Hospital at the present time contains 380 beds, and this number will be increased in a short time. The Hospital is recognised as a complete Training School for Nurses. The Resident Medical Staff will number three. A wide experience of Medical and Surgical work is to be obtained. It is desired that candidates shall have had practical experience of Surgery and Anæsthetics. It may be stated that there are many opportunities in the neighbourhood for golf and other sports.

Application forms, which must be properly filled in, and returned to me not later than March 1st, together with further particulars of the appointment, can be obtained from the undersigned on receipt of a stamped addressed foolscap envelope.

By Order,
W. HARDING ROBERTS,
27, Victoria Avenue, *Clerk.*
Southend-on-Sea.

Bristol General Hospital.

The Committee invite applications for the following appointments, which become vacant on April 1st next:

Two HOUSE PHYSICIANS, Two HOUSE SURGEONS, RESIDENT OBSTETRIC OFFICER, HOUSE SURGEON to the Special Departments, and a CASUALTY HOUSE SURGEON.

The appointments will be *for five months at* salaries at the rate of £80 per annum, with board, residence, etc., provided in the Hospital.

Candidates must be registered under the Medical Acts, and produce testimonials of good personal character and ability, and must have recent experience in the administration of anæsthetics.

Forms of application, etc., to be obtained from the Secretary, must be returned completed, with copies of testimonials, addressed to the undersigned, on or before Monday, March 11*th* next, from whom further particulars may be obtained.

THOMAS W. GREGG, Secretary.

West London Hospital,

Hammersmith Road, W.6. (225 Beds.)

Applications are invited for the post of HONORARY ASSISTANT ANÆSTHETIST. Candidates are required to be registered under the Medical Act, to send applications, with copies of testimonials, so as to reach me not later than Thursday, March 21st; to attend the Medical Council Meeting at 4.30 p.m. on Friday, March 22nd, and prior to that date to call upon and send copies of their applications and testimonials to each member thereof; to abstain from canvassing, but nevertheless to send copies of their applications and testimonials to the Members of the Board of Management, who will elect on Tuesday, March 26th, at 5 p.m., when candidates must be in attendance.

H. A. MADGE, Secretary.

Ancoats Hospital, Manchester.

RESIDENT SURGICAL OFFICER.

Notice is hereby given that this post becomes vacant on June 1st next, and the vacancy will be advertised early in May, when applications will be invited from qualified gentlemen, preference being given to those holding an F.R.C.S. degree.

Ancoats Hospital, Manchester.

HOUSE SURGEON.

Applications are invited for the post of House Surgeon, which becomes vacant on March 31st. Appointment for six months. Salary £100 per annum, with board, apartments, washing. Apply, not later than March 4th, stating age, qualifications, experience (if any), to the General Supt. and Secretary.

St. James' Hospital, Leeds.

Applications are invited for the filling of a vacancy in the staff of HOUSE PHYSICIANS and SURGEONS at the above Hospital. Applicants must be fully qualified and registered. The Hospital is one of 1,126 beds, with special departments for Radiology, Pathology, Midwifery, and Diseases of Children. There are, in addition, 320 beds in separate Mental Wards. The staff consists of a Medical Superintendent, a resident Medical Staff of six, a Pathologist, a Radiologist, and Visiting Physicians and Surgeons.

The successful applicant will be required to act as House Physician and Surgeon under the Medical Superintendent and the Visiting Staff, and to perform such other duties as the Medical Superintendent may direct. The term of appointment is limited to two years.

Salary £200 per annum, with board, apartments, and attendance, subject to deductions under the Poor Law Officers Superannuation Act, 1896.

Applications, stating qualifications, and giving particulars of present and prior occupations, together with copies of three recent testimonials, must be received by me not later than 10 a.m. on Saturday, March 9th, endorsed "House Physician and Surgeon."

Selected candidates will receive due notice to attend.

Poor Law Offices, JAMES H. FORD,
South Parade, Clerk to the Guardians,
Leeds. Township of Leeds.
February 18th, 1929.

Royal Berkshire Hospital.

The Board of Management invite applications for the appointment of HONORARY MEDICAL OFFICER in charge of the Electro-Therapeutic Department. Candidates must be Fellows or Members of the Royal College of Physicians, London, or Medical Graduates of one of the Universities of the British Empire, and must be registered.

The elected candidate will be appointed for the period ending on the third Tuesday in January, 1930, and will be eligible for re-election. Canvassing by or on behalf of a candidate will disqualify him.

Candidates are required to provide eighty copies of their application and testimonials, which must be addressed to the Secretary, and reach him not later than March 7th. No testimonials will be required from candidates who are members of the existing Medical Staff. The election will be held on March 19th.

Reading, HERMAN BURNEY,
February 23rd, 1929. *Secretary.*

St. Peter's Hospital for Stone, *ETC.*,

Henrietta Street, Covent Garden, W.C.2.

Applications for appointment as HOUSE SURGEON are invited from male candidates with previous experience in a similar office at a General Hospital. The salary offered is at the rate of £75 per annum, with board, lodging, and laundry.

At the expiration of his term of office, which is for six months from April 1st, the House Surgeon, subject to the recommendation of the Medical Staff, is appointed Resident Surgical Officer for a similar period of six months.

Applications, accompanied by copies of testimonials, will be received by the undersigned not later than first post on Wednesday, March 6th.

BEECHEY ROGERS, Secretary.

Dorset Mental Hospital,

DORCHESTER.

SENIOR ASSISTANT MEDICAL OFFICER.

Applications are invited from candidates duly qualified, registered, and unmarried. Commencing salary £400, rising by two yearly increments of £25 to £450, with board, apartments, laundry, and attendance.

Excellent laboratory facilities exist with skilled assistance for research and clinical medicine. (900 Beds.) The appointment is subject to the provisions of the Asylum Officers Superannuation Act, 1909.

Applications, stating age and qualifications, with copies of recent testimonials, should be sent to the Medical Superintendent at once.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (5 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. PARTNERSHIP.—SOUTH COAST.—In a fashionable watering-place, the two-thirds share is for disposal in a mixed Homœopathic and Allopathic (roughly half and half) good-class non-dispensing, non-panel conection, in which there is a certain amount of surgery, and ingoing partner should be an operating surgeon. Receipts average over £3,600 p.a. Fees 10/6 upwards. Very little midwifery Large and suitable maisonette available, with ample accommodation, in excellent position. Rent, on lease, £250 p.a. Premium for share 1½ years' purchase.
2. SURGICAL PRACTICE.—SOUTH-WESTERN COUNTY.—Large Hospital Town.—A purely Surgical Practice, held by Vendor over 20 years, is for disposal owing to ill health and retirement. Income over £4,600. Consultations 10/6 to £2 2s. Operation fees 20 to 30 gns. and over. Detached residence, with large accommodation and modern conveniences. Rent, on lease, £250 p.a. Premium 1½ years' purchase. Six months' introduction, or longer if required. A Nursing Home is run, in connection with the Practice, which shows a profit of £1,000 p.a., and which is also for disposal at a moderate price, with the furniture at a valuation. Premises can be rented on lease.
3. PARTNERSHIP.—Within 3 miles North-West of Charing Cross.—The half share of an old-established middle and working-class Practice, averaging about £2,100 p.a., including panel of 1,300. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 bedrooms, bathroom, kitchen, etc. Small garden. Net rental, on lease, about £60 p.a. Premium 2 years' purchase.
4. HAMPSHIRE.—PARTNERSHIP.—Third share of an old-established unopposed Country Practice, in very pretty district within a few miles of a large town, and producing nearly £2,600 p.a., including appointments £130, and panel of 1,520. Visits 5/6 to 21/-. Mids. 2 to 10 gns. Large house (having eight or nine rooms, with garden, etc.), which must be purchased, or ingoing partner could reside in rooms until a smaller one becomes available. Premium 2 years' purchase, half down and balance in 12 or 18 months.
5. KENT.—Old-established Country PRACTICE, situated in very favourite locality within 5 miles of the coast. Income for past 12 months £1,030. Surgery fees 5/6 upwards, visits 5/- to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
6. NORTH STAFFORDSHIRE.—Old-established mixed general Country PRACTICE, situated in very delightful district, and offering scope. Average income about £1,000, including Poor Law appt. and panel of 660. Fees 5/6 to 10/6. Good house, on lease, rent £84 p.a. Excellent schools within reach. Premium 1½ years' purchase.
7. BUCKS.—GROWING COUNTRY DISTRICT.—Old-established mainly middle and working-class PRACTICE. Income for the last year £550, with ample scope for increase. Fees 2/6 to 7/6 Little midwifery. Good freehold house, price £1,500, part on mortgage. Sport of all kinds. Knowledge of refractions advantageous. Premium £850.
8. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share (and up to one-half in two years' time) is offered in an old-established mixed general Practice, averaging about £2,000 p.a., with good scope. Non-panel at present, but ingoing partner should undertake this work. Fees 5/6 to 7/6, a few at 15/-. Little midwifery 3 to 10 gns Suitable house can be bought. Sport of all kinds. Premium 2 years' purchase.
9. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
10. LONDON, S.E. (CROYDON AREA).—Old-established rapidly increasing middle-class PRACTICE. Income for immediate past year over £1,300, including panel of 700. Surgery fees 2/6 to 5/-. Visits 5/6 to 10/6 Thirty midwifery cases yearly from 3 to 10 guineas. Very commodious house on lease, with 11 years to run, rent £70. Premium £2,000.
11. LONDON, WEST.—PARTNERSHIP.—A half share in an old-established mixed general Practice. Average income for the last three years about £4,000. Panel of 3,250. Fees 2/6 to 7/6, visits 5/6 to 10/6, and a few at 21/-. About 30 midwiferies at from 3 to 10 guineas. Convenient house in good position Held on lease (with no ground rent) with 25 years to run. Price £1,750. Premium £4,000. Must be Scotch or English.
12. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 5/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
13. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
14. SOUTH-EAST OF ENGLAND.—COAST TOWN.—Small but increasing PRACTICE, at present producing about £500 per annum, with good scope. Panel of 420. Suitable house available. Rent £52 p.a. Premium £500, part down, and balance by instalments
15. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 5/6 to 21/-, medicine extra. Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium £750.
16. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRACTICE, producing for the past twelve months £768, including panel of 525, and appointments worth over £60 p.a. Advice and medicine chiefly 5/6 to 7/6, visits 5/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 guineas. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, and good professional rooms and usual offices. Hot water supply, electric light Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
17. LANCASHIRE.—SUBURB OF LARGE TOWN.—Old-established PRACTICE, held by Vendor 30 years. Average income for the past twelve months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/-. Very good house, standing in its own grounds, and containing 3 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments
18. LONDON, S.E.—Outlying Suburb.—Very well-estab. growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of 2,120. Appts. worth about £60 and stated to be transferable. Fees 2/6 to 7/6. Midwifery from 3 gns (about 40 cases yearly. Moderate expenses Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden Brick built garage. Price for freehold £1,500 Premium £4,500
19. SOUTH OF ENGLAND.—FAVOURITE SEASIDE RESORT.—Mainly better-class PRACTICE, producing for the last twelve months about £700, and rapidly increasing. Panel of 150. One appt. worth about £40 p.a. Fees 3/6 to 7/6. Only a few cases of midwifery, 2 gns. upwards. Good house in excellent repair, with 2 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Price for freehold £2,300 Premium £1,400.
20. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, situated in good hunting centre. Gross cash receipts for past 12 months about £1,000 p.a., including panel of 600. Advice and medicine from 3/6, visits 3/6 upwards, with medicine extra. Lowest midwifery 2½ gns. Exceptionally attractive house, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1¼ acres, and 12 acres of grassland. Recently re-decorated throughout Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
21. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools Price for practice and house £3,000
22. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200 Premium 1½ years' purchase.
23. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£60), with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented. Prem. 1½ years' purchase.
24. WILTSHIRE.—Unopposed old-estab. Country PRACTICE, situated in very pretty district and averaging £700 p.a., including Union appt. £70, and panel producing £450. Nearest opposition 5½ miles. Railway station 1 mile. House stands in own grounds of 1¼ acres, with tennis court, garage, etc., and contains surgery, 3 reception, 5 or 6 bedrooms, bathroom (h. & c.). Electric light plant installed. Vendor's freehold, price £2,600, all of which could remain on mortgage if wished. Premium £1,050.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

$$C_8 H_{10} N_4 O_2 + H_2 O$$

THE injurious action of caffein, to which the ailing, convalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance

H.A.G. COFFEE CO. LTD.
40 Theobald's Road, London, W.C.1

A GREAT STRIDE IN ANÆSTHETICS

For many years Anæsthetists have demanded a pure Ether made from pure Rectified Spirit, but have not felt justified in paying the exorbitant duty which had to be included in the price. From this derived the constant fear that the impurities such as Wood Spirit, Pyridine, etc., laid down by the Customs as necessary denaturants in the preparation of Ether at an economic price, had not been completely eliminated in the final product and the feeling that in troublesome cases the Ether used might be suspected.

Howards of Ilford have now succeeded in banishing these troubles entirely and are able to supply their Standard Æther, *manufactured entirely from Duty-free Rectified Spirit* which has never been in contact with *any* deleterious or objectionable denaturant at *any* stage, *without extra charge.*

COAGULEN-CIBA IN HÆMORRHAGE

Five correspondents in *The British Medical Journal*, July 28th, 1928, p. 182, testify to the value of Coagulen-Ciba in Hæmophilia.

Reports on the successful administration of Coagulen-Ciba were published in *The Lancet*, October 31st. 1925, p. 918, Intestinal Hæmorrhage; *The Lancet*, June 13th, 1925, p. 1238, Hæmoptysis treated by Intrapulmonary Injections; *The Lancet*, January 24th, 1925, p. 176, Hæmorrhage following Tonsillectomy.

Three cases (two Hæmoptysis, one Bowel Hæmorrhage) successfully treated with Coagulen-Ciba by the mouth are reported in the *Journal of the Royal Naval Medical Service*, No. 1, Vol. XII, pp. 64-65.

Full particulars and reports to Physicians on request.

Something New in Surgical Literature

WE invite the attention of the profession to Nelson's "Loose-Leaf Living Surgery." It consists of 7 volumes containing, so far, 5,000 pages, surveying the entire scheme of modern surgery. It is bound in loose-leaf style so that pages may be added under any heading. At least twice a year a résumé of the latest world knowledge on surgery is printed and sent to subscribers for insertion in their books.

The editor-in-chief is ALLEN O. WHIPPLE, M.D., Professor of Surgery, College of Physicians and Surgeons, Columbia University, assisted amongst others by J. M. T. FINNEY, Professor of Clinical Surgery, Johns Hopkins Hospital. Men of such calibre as our own A. J. WALTON, PUTTI of Bologna, GASTON LABAT of Montpelier University, and THORKILD ROVSING of Copenhagen contribute.

The volumes are divided as to the main subjects along the following lines:—Vol. 1: Pathology, Technic, Legal Relations, etc. Vol. 2: Head and Neck, Tuberculosis, Diabetes, Nervous System, etc. Vol. 3: Chiefly Orthopaedic. Vol. 4: Heart, Breast and Lungs, etc. Vol. 5: Abdominal. Vol. 6: Urology. Vol. 7: Gynecology. There are thousands of illustrations of a strikingly clear and informative character.

If you are interested it will be a pleasure to send you any one or more of the books (even the complete set) to look over without asking you to assume the slightest obligation to purchase.

Request for Free Examination.

To THE WAVERLEY BOOK COMPANY, LTD.,
96-97, FARRINGDON STREET,

Prescribed in numerous cases *of* *nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Novopine
Sparkling Pine Bath Tablets

WHOOPING COUGH

Vapo-Cresolene Est. 1879
Sold by Chemists
Write for descriptive Booklet No. 67A.

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

Analysis of the Cresylic Acid Content of Lysolats

There is no need to remind Medical Men that the lysols on the market represent varying grades of cresylic acid, many containing a high percentage of impurities which attack and irritate the tissues. For the information of doctors who insist upon the highest grade of cresylic acid, the makers of Lysolats wish to make known the following analysis of the cresylic acid content of their solid form of lysol.

Composition. 99-100 per cent. (A mixture of 50 per. cent. Meta-Cresol, 25 per cent. Para-Cresol, 25 per cent. Ortho-Cresol, with small quantities of Homologues.) Impurities do not exceed 0.1 per cent., including water, as follows:—

Pyridine, 0.05 per cent. maximum.
Naphthalene, 0.05 per cent. ,,
Light Oil, nil.

Specific Gravity. 1.040 to 1.047 at 15.5° Cent.

Boiling Point. Not less than 90 per cent. distills between 195° and 205° Cent.

Odour. Pleasant. Clean and free from sulphuretted hydrogen.

Solubility in Caustic Soda. 10 c.c. dissolved in 40 c.c. of caustic soda solution (of a specific gravity of 1.060) gives a clear solution.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney Street, London, S.E.1.

Lysolats
PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

INSULIN "A.B."

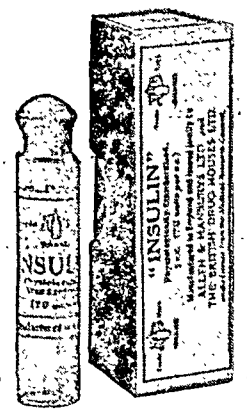
TRADE A B MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Sanatogen Strengthens but does not Irritate

The value of Sanatogen as a tonic food lies in its ready absorption. Even the weakest stomach can easily digest Sanatogen. For this reason Prof. Ewald of Berlin University, amongst others, has frequently given it in typhoid fever and reports that it is promptly absorbed during the febrile period with apparently the same ease as under normal conditions.

Writing in "*The Medical Press and Circular,*" a leading authority says:

"*Sanatogen is readily absorbed by the stomach and has an immediate and remarkable effect, shown by a steady increase of body-weight and of muscular strength and energy.*"

Prescribe 'Mistol' for the Nose and Throat.

MISTOL has proven especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Mistol consists of menthol, eucalyptol, and camphor carefully combined in proportions recommended by leading nose and throat specialists. A specially prepared petroleum base keeps the soothing, healing ingredients in direct contact with the mucous membrane for a considerable length of time. Moreover, it prevents it being easily washed away by the natural secretions.

Mistol and the Mistol Dropper are a real advance in nose and throat therapy. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. Unlike douches, Mistol avoids any possibility of sinus trouble. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Sold in original sealed cartons containing a—

Mistol
(*Registered Trade Mark*)

Two-ounce Bottle and Mistol Dropper.

Purity in Anæsthetic Ether

The advantage of employing only the purest ether is now generally recognised.

The British Drug Houses Limited, *three years ago*, after prolonged negotiations obtained the concession from the Commissioners of Customs and Excise permitting them to use for the manufacture of ether for medicinal purposes a special duty-free rectified spirit to which no methylating agent had been added. This ether was subjected to further extreme measures of purification, by methods evolved in the B.D.H. Laboratories, and thus was Aether Puriss. B.D.H. produced and placed on the market.

Aether Puriss. B.D.H., therefore, from the beginning, and throughout the whole period of its production on a commercial scale, has been manufactured entirely from pure duty-free rectified spirit to which no methylating agent has been added.

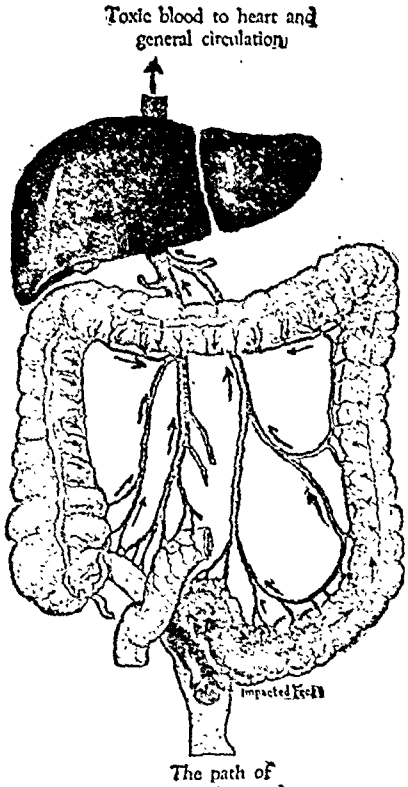
An entirely new preparation for effectively cleaning artificial teeth. Can be used on the most delicate dental plate with complete safety and satisfaction.

Antiseptic. *Convenient in use.*

Dissolves Intestinal Toxins



The path of Intestinal toxemia

Not the least valuable of its properties is the behaviour of Nujol toward intestinal toxins.

If a watery solution of indol be shaken up with Nujol, more than half the indol is quickly taken up. Nujol readily dissolves this and other waste and poisonous substances, many of which are more soluble in Nujol than in water. Once absorbed in Nujol they cannot be absorbed by the system, as Nujol itself is non-absorbable.

The brownish colour of Nujol as seen in the stool is partly due to toxins which it holds in solution.

Nujol is a safe and effective treatment in all types of constipation and intestinal toxemia.

FELLOWS MEDICAL MANUFACTURING CO., Inc.
26 Christopher Street, New York, U. S. A.

For Ill Conditions of the Gastric Tract

"Alocol" is the practitioner's safeguard when alkaline medication is indicated. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia, and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed, which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

The advantages of "Alocol" are therefore manifest. It neither hinders proteolysis nor causes destruction of any food element or factor. Prolonged exhibition interferes in no way with the normal putrefactive function of the gastric juices, or with the regular processes of nutrition.

"Alocol" is regarded as a specific in the treatment of hyperchlorhydria, whilst for all forms of fermentative dyspepsias, with gastro-intestinal flatulence, acid eructations, and other symptoms common to gastric disease, its influence is beneficial to the highest degree.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

Intestinal Disinfection

PREVENTION OF CANCER

ONE of the most noted authorities on Alimentary Toxæmia is firmly convinced of the importance of this condition in the production of Cancer.

The irritant effects of the stagnating contents of the bowel on the intestinal mucous membrane, accompanied as it often is with ulceration, is obviously a cause of Cancer in the bowel itself. According to this writer, the toxins absorbed produce atrophic changes in the breast and other organs which are specially prone to be followed by Cancer.

There are grounds, therefore, for hoping that the use of the most efficient of all intestinal disinfectants—Kerol—for prevention and cure of alimentary toxæmia, will do much to prevent the occurrence of Cancer.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

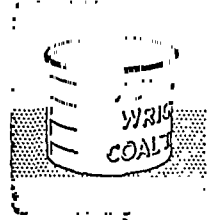
The name is everything—"WRIGHTS" LYSOL

It is your patients' guarantee that the Lysol is pure, safe, and certain in action.
Wright's Lysol is highly refined, standardised, and strictly controlled by the Rideal-Walker test. Repeated independent tests have proved that its high quality never varies.
Cheap Lysols—ungraded Lysols—Lysols made by irresponsible firms—these are dangerous. Insist on *Wright's* Lysol, the accepted standard of excellence.
British owned and made by the makers of the world-famed Wright's Coal Tar Soap.
Used by leading Hospitals all over the world.



A handy graduated measure is provided with every bottle.

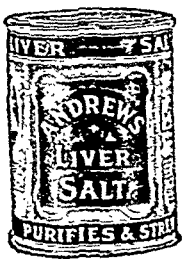
Streets 50

Intestinal Disorders consequent upon Bronchial Infection

Partly owing to the considerable amount of sputum inevitably swallowed by the patient in bronchial affections (especially in children) disorders of the digestive organs may be produced.

A suitable diet, and a free daily evacuation tend to prevent these disorders.

Andrews Liver Salt by its effervescence freshens the mouth (often so dry in bronchitis) and by its antacid action counteracts gastric catarrh. By producing an easy evacuation safe even in the presence of myocardial degeneration, it removes the organisms introduced by the swallowed sputum.



Dose: ½-3 *teaspoonfuls in a glass of water.*

N.B. *A large size tin will be sent free on request to any member of the medical profession.*

Alternative Methods in
PROPHYLAXIS & TREATMENT
OF
INFLUENZA & CORYZA

DETOXICATED ANTI-INFLUENZA AND ANTI-CORYZA VACCINES

These Vaccines have been used with great success for several years. Their outstanding feature is the absence of reaction, which makes them especially useful in actual treatment and in the case of hypersensitive patients.

The composition of these Vaccines is highly compound; in addition to other organisms the Influenza Vaccine contains 15,000 millions and the Coryza Vaccine 5,000 millions, per c.c., of the *new Streptococcus isolated from the blood of influenza cases.*

ORDINARY ANTI-INFLUENZA AND ANTI-CORYZA VACCINES

Some Practitioners consider that a slight reaction has definite therapeutic value, and these Vaccines have been prepared to meet their requirements. They have the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY

(For local application to the nose and throat)

For patients who object to Vaccine treatment by subcutaneous injections, and for children, this Local Immunity Product is particularly indicated. It contains the Influenza Streptococci in addition to the various Coryza organisms, and is, therefore, valuable as a prophylactic against Influenza Colds.

¶ *Practitioners desiring further information regarding these Products are invited to write to:*

TRADE 'BYNOL' MARK

"A Perfect Combination of Malt Extract with Cod-Liver Oil"—*B.M.J.*

'Bynol' contains 30% by volume of the 'Allenburys' 'Perfected' Cod-Liver Oil intimately commingled with the 'Allenburys' Malt Extract, thus producing a rich, easily digestible and palatable product. Cod-Liver Oil is the richest available natural source of the fat soluble growth-promoting and anti-infective vitamin A and the anti-rachitic vitamin D. This season's oil has been tested independently in the laboratories of the Pharmaceutical Society of Great Britain, and passed as fully active with regard to the vitamins A and D.

Each jar bears a copy of the Society's Certificate.

Issued in wide-mouthed jars at 2/3, 4/- and 7/6

Clinical trial sample will be sent post free to members of the Medical Profession

RADIO-MALT

The unique vitamin preparation

The value of Radio-Malt in medical practice is generally recognised, and it is being prescribed by an ever-increasing number of physicians throughout the world.

Radio-Malt is definitely anti-infective; it promotes healthy growth, assists correct development of bones and teeth in the young, and corrects faulty calcium metabolism in patients of all ages.

Its properties are due to its content of Vitamin A, Vitamins B_1 and B_2, and Vitamin D, all of which are manufactured under strict scientific control in the B.D.H. laboratories, and are incorporated in Radio-Malt in standardised amounts.

AN ANCIENT JAPANESE MASK REMINISCENT OF A "PACIFIC AGE" WHICH INFLUENCED VERY EARLY JAPAN IN COMMON WITH NEW GUINEA, THE PHILIPPINES, ALASKA AND MEXICO.—The islands which constitute Japan lent themselves naturally to that mingling of peoples, evidence of which is so clearly visible in Japanese physiognomy and art. Immigrants from Siberia, China, Malaysia and Polynesia met here in the days before history, and again, later, the islands formed a link in the traffic between East and West. The mask here reproduced illustrates an extremely early period of Japanese life and art and relates them to the whole Pacific area. Its kinship with similar objects from Polynesia, Malay, New Guinea, Borneo, the Philippines and Alaska is very marked, as it is also with the Aztec and Hawaiian masks. All have the slanting eyes and prolonged nose, and were used in sacred dances.

A British Medical Association Lecture

ON

MINOR ORTHOPAEDICS OF THE FEET IN GENERAL PRACTICE.

DELIVERED TO THE NORTHERN COUNTIES OF SCOTLAND BRANCH, NOVEMBER 2ND, 1928,

BY

JOHN FRASER, M.D., F.R.C.S.ED.,

REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH, AND SURGEON TO THE ROYAL INFIRMARY.

THIS address includes the consideration of a number of conditions apparently so simple that some may feel that there is nothing new to be said about them; but I have noticed that minor orthopaedic disabilities are remarkably common, that among the work of a young consultant they form a considerable proportion of his material, and since they come to the institution and the consultant, I infer that they are a source of trouble and anxiety to the man in general practice. When I add that many of these conditions are among the most difficult to treat and to cure, I have justified, I hope, the choice of my subject. I propose *to illustrate what I have to say by short abstracts* from case notes, and, so far as possible, to demonstrate the conditions to which I refer.

INGROWING TOENAIL.

My first patient is a woman, and the reason of her visit is the presence of a painful ulcer on the lateral nail border of the great toe. It seems a small thing, but to my patient, who has been seriously affected by the dancing craze, it is a disaster. With Cowper she would no doubt exclaim:

> "O may I live exempted . . .
> From pangs arthritic that invest the toe
> Of libertine excess."

As a matter of fact, she was suffering from an ingrowing toenail, *one of the most painful and distressing of the* minor maladies of the feet.

So perfect are the provisions which Nature has made to guard against this disaster that the sufferer must have flagrantly destroyed one or more before Nemesis overtook her. If you examine the nail-fold (Fig. 1) you will find that *these provisions are two*—the edge of the nail is curled upon itself so that a convex surface is opposed to the skin surface, and, as though that were insufficient, the skin in contact with the nail-edge is of a more horny texture than that around—the result of the deposit of

FIG. 1.

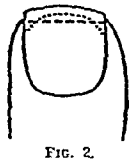

FIG. 2.

FIG. 1.—The toenail on coronal section. Note the infolding of the nail-edge, and the special epithelium with which it makes contact.

FIG. 2.—Cutting a toenail. The nail should be cut at right angles to its long axis—*not* in a curved manner.

a considerable amount of eleidin granules in its cells. These safeguards are present in both foot and hand, but, owing to the relatively greater pressure which the foot-nails have to bear, they are more efficiently developed in the latter situation.

An ingrowing toenail results from one or both of two errors: either the nail is cut convexly so that the protective infolding of its edge is *destroyed, or the special* stratified epithelium is removed, and its safeguard thus eliminated. My patient had been guilty of both errors. She had been cutting her nails convexly, and at the same time, in order to improve the local appearance, she had been using a preparation containing salicylic acid, which she had been brushing over the nail-fold, and so removing the valuable horny layer. Is it any wonder that, as her nail grew, its now sharpened and unfolded edge, coming into contact with a delicate and unprotected epithelium, produced at the point of contact a most painful and intractable ulcer? (Fig. 2.)

Treatment of Ingrowing Toenail.

What was to be done? To remove the toenail is rather a desperate remedy; it is certainly a very painful one. It may involve weeks of crippling, and should only be resorted to when all other measures have failed. Cutting away that portion of the nail which impinges upon the ulcer is the procedure perhaps most frequently adopted, and, if it is accompanied by careful packing of the ulcer surface with an antiseptic gauze or wool, it may ultimately prove successful; but it has the risk that the natural infolding of the nail may not reappear, in which event ulceration is sooner or later bound to recur.

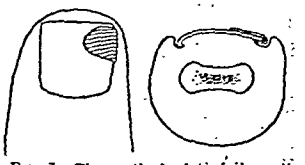

FIG. 3.—The method of tinfoil application in the treatment of ingrowing toenail.

In my experience there are two simple and efficient remedies, neither of which is perhaps sufficiently known. *The nail-fold may be protected by restoring the convex* nail-edge, which is done by wrapping around the offending nail-edge a small oval-shaped piece of soft tinfoil, so arranged that a fraction of it lies on the under surface, the remainder on the nail surface. It is fastened in place by *a drop of sterile glue or strong collodion. A fragment of* Stent wax is sometimes used instead of the tinfoil, but it is brittle and apt to break. While the protection is in place the ulcer is lightly packed with a spirit solution of one of the aniline dyes, this being used because it increases *the cornification of the epithelium and so stimulates the* formation of the protective layer. (Fig. 3.) The second simple remedy is sometimes known as Webb's wire, which acts by maintaining a constant separation between nail-fold and nail-edge, and I can vouch for its efficacy in curing the early stage of this troublesome ailment.

HAMMER-TOE.

My second patient presents herself because of the common and troublesome condition of hammer-toe. It has affected the second toe, as it usually does, because it is the longest of the outer four, and is liable to be displaced and cramped if any lateral displacement occurs in the great toe (Fig. 4). In this patient's case the deformity is well marked; in other words, there is pronounced flexion of the proximal intraphalangeal joint; it is not congenital, and a glance at her shoes shows the cause in the badly shaped and centrally pointed type of sole. It is a hopeless task, I am afraid, to expostulate with women on this score; the majority of them fully realize the risks, but *feel, in the words of the old Scottish* proverb, "As weel be oot of the warld as oot o' the fashion."

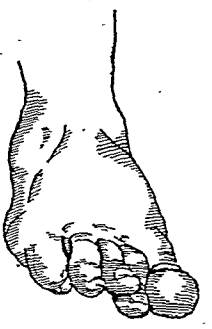

FIG. 4.—A hammer-toe deformity affecting the second toe of the right foot.

Treatment of Hammer-toe.

I suggest to the patient that a simple minor operation will prove the most satisfactory, and in the long run the most rapid method of cure. But operation she will not hear of, and conservative measures must therefore be adopted. What are they to be? and what prospects do *they offer of improvment or cure? Answering the latter* question first, there can be no doubt that, if the case is an early one, and if efficient conservative measures are adopted and persevered in, good results are obtained. What are the efficient conservative measures? My own choice is in favour of what is termed the "cradle method."

It is carried out by means of two narrow strips of sticking-plaster, and is sufficiently illustrated in the diagram. (Fig. 5.) This procedure has great advantages: it is simple and comfortable, but, above all, the improvement which it induces is progressive, for with every step the patient takes there is a stretching of the contracted tissue and an improvement in the position of the parts. By this simple means an operation is often obviated.

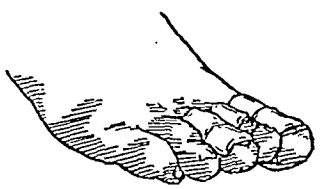

FIG. 5.—A hammer-toe deformity treated by the "cradle" method.

There are other conservative measures, but I do not think they are so good as the "cradle." There is the insole provided with an elastic loop into which the contracted toe is inserted. It is applied inside or outside the stocking, but if the second course is chosen the stocking must be knitted so that the affected toe occupies a single compartment. Another method is the use of a light aluminium splint strapped underneath the toe and extending from its tip to the level of the metatarso-phalangeal joint. Both of these methods, however, are, in my experience, uncomfortable, and by no means so efficient as the cradle method.

If operation is adopted it is simplicity itself—a transverse incision on the dorsum of the flexor joint, excision of a wedge carrying the articular surfaces and reposition of the toe in a straight attitude, the shortened tendon being divided by tenotomy. Thereafter (and this is an important detail which is often neglected) the toe must be splinted so that ankylosis occurs at the point of excision, the splintage being provided by a narrow strip of aluminium strapped to the under surface of the toe.

As the result of the hammer-toe this patient has two troublesome corns. They are at the points of maximum pressure—on the convexity of the interphalangeal flexion deformity and on the tip of the terminal phalanx immediately below the nail. They will in all likelihood disappear when the error in position is corrected, but, in case they do not, they will yield to an application of 10 or 15 per cent. salicylic collodion, or they may be pared and excavated with a sharp knife and a covering of newskin applied. The last detail is important, for attention to it after removal of the corn will often prevent recurrence of the trouble.

HALLUX VALGUS: ITS CAUSE.

My third case is an example of an exceedingly common error. It is the hallux valgus deformity of the first metatarso-phalangeal joint, the great toe being deflected outwards so that it lies over or under the second toe (Fig. 6). The patient is a woman, and after recounting the pain and discomfort from which she is suffering because of the pressure of her shoe upon the inflamed bursa or bunion overlying the prominent head of the first metatarsal bone, she inquires as to the cause of the condition. It has been said that an undue activity of growth in the epiphysis at the base of the first metatarsal bone explains the occurrence of a certain proportion of cases. This may be so, but in the majority the cause is flat-foot, with which a hallux valgus of any degree is almost invariably accompanied. The sequence of events is probably as follows: The foot adopts an attitude of valgus error, and there come into play two influences which lead to the development of the hallux valgus deformity: First, as the valgus error becomes established an attempt is made to restore the balance by bringing into play the short muscles of the sole. Into the fibular side at the base of the proximal phalanx of the great toe three muscles are inserted, the two adductors (oblique and transverse) and half the flexor brevis. Their influence is to pull the toe into a valgus attitude. The abductor might have opposed this influence, but it is already weakened by the flat-foot error, and the result is the gradual development of hallux valgus. The second influence is in relation to the shoe. As the flat-foot develops the inner portion of the shoe—the golosh and the sole waist—stretches and weakens, the foot arch falls, and the valgus error of the foot is more fully established, but the toes are fixed in the anterior part of the sole, and therefore, as the inner side of the foot falls inwards the great toe is deviated outwards, and the hallux valgus is thus more fully established. I have dealt with this question in some detail because it has an important bearing upon the treatment of the condition, and I am anxious to establish the truth of the statement that a hallux valgus does not usually develop without the accompaniment of a flat-foot error.

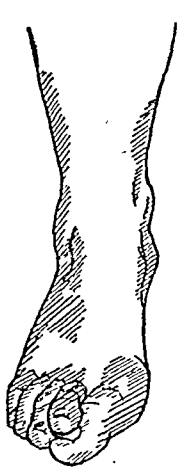

FIG. 6.—A hallux valgus deformity of the great toe.

Treatment of Hallux Valgus.

What can I do to relieve this unfortunate patient? As it happens, the condition is not sufficiently advanced to demand operative intervention, and I accordingly concentrate my attention on conservative measures. I recommend certain alterations in the shoe, and the wearing of a remedial appliance while the patient is resting in bed. The alterations of the shoe are important, for not only do they exert a curative effect upon an early case, but they afford enormous relief to the discomfort and suffering of the individual. Here are the instructions. The shoe must be reasonably straight along its inner side. Where the prominent head of the first metatarsal would naturally impinge upon the boot upper this must be softened or even cut out to allow the insertion of a specially thin piece of material. It is wrong to allow the continuance of pressure upon the tender prominence, as this will only increase the development of the bursa and accentuate the deformity. The golosh must be strengthened by inserting a strip of strong leather from the heel across the boot or shoe waist to behind the head of the first metatarsal bone, and support is given to the longitudinal arch of the foot by inserting and cementing to the sole a rubber instep pad. These details are, of course, designed to improve the flat-foot error. Perhaps the most helpful manœuvre of all, however, from the patient's point of view, is the attachment to the under surface of the sole of a metatarsal bar half an inch broad and a quarter of an inch in depth. It is placed, like the bars of a football boot, across the sole, immediately behind the metatarso-phalangeal joint, and it gives the most wonderful measure of relief, because it takes the body weight off the affected and painful joint.

Many other suggestions of boot alteration have been put forward, but they are not of great practical value. One (the attachment of a stud to the upper surface of the sole so that it projects between the first and second toes) may at first sight appear attractive, but those who have tried to coax the delinquent toe into its stall have realized how tantalizing and wellnigh impossible a task it is; and if they have by any chance achieved the seemingly impossible they have realized how great is the discomfort which results on attempting to walk. If any additional manœuvre is of value, it is the provision of a specially woven stocking made like a mitten, with a special compartment for the great toe. I have heard the late Professor John Chiene recommend this procedure, and it has a certain practical value.

The time to adopt more active corrective measures is when the patient is bootless and resting, and there is upon the market an efficient appliance designed for this purpose. A light firm splint extends along the inner side of the great toe and medial border of the foot. It is secured to the toe by means of a broad elastic webbing loop, and the distal portion is fastened to the metatarsus by a broad strap and buckle. In applying the splint the toe is first inserted into the elastic loop, and the correction is then produced by placing the remainder of the splint in line with the side of the foot and securing it there by its strap and buckle.

With the question of operative intervention, should it become necessary, I do not propose to deal beyond saying that any procedure which may result in shortening the length of the longitudinal arch is bad in so far as it must weaken the foot. For this reason the

head of the metatarsal bone should not be removed. It may be sufficient to remove the prominence from the inner side of the metatarsal head, but, if something further is required to secure correction, it is better that it should concern the base of the first phalanx than the head of the metatarsus.

HALLUX RIGIDUS.

My fourth problem is a peculiarly troublesome one. The patient is a keen walker—in fact, walking is his chief exercise and recreation. You can imagine his distress when he finds that his activities are becoming seriously crippled owing to stiffness and pain in the joint of the great toe of his right foot. He has, in fact, a well-marked hallux rigidus, and it is impossible to secure any degree of dorsiflexion in the metatarso-phalangeal joint of the toe.

It may be asked why such a seemingly simple error should be so crippling in its effects. We find the answer when we analyse the process of walking. As a stride is taken the heel and the outer side of the foot make contact with the ground; the pressure is momentary, for, as the body passes forwards over the centre point of the foot the weight is transferred to the forepart of the foot, and more particularly to the prominent heads of the first and fifth metatarsal bones. As the body continues to move forwards and preparations are made for the next stride, the heel is raised off the ground, the weight is borne by the forepart of the foot immediately behind the toes, while all the toes, but particularly the great toe, flex at the metatarso-phalangeal joints, and the actual impulse which carries the body forward for the succeeding stride is, in part at least, afforded by the flexed great toe levering the body forward against the fulcrum of the ground. It is evident now how disastrous must be the consequence if the metatarso-phalangeal joint of the great toe is painful or in any measure fixed.

Etiology of Hallux Rigidus.

Invariably there comes the question, How has this arisen? Injury can be excluded in this case, though it is evident that there are instances in which a hallux rigidus may follow injury to the joint or the neighbouring bones. There has been a history of rheumatism, and this may play some part in the secondary changes of the part, but the real explanation is to be found in the statics of the foot behind the region of the joint. In the case under discussion there had been a severe influenzal illness some months preceding the development of the foot error. Walking and standing were resumed with limb muscles of a poor tone, and as a result a longitudinal flat-foot of a somewhat acute type developed. At once the line of gravity altered, and instead of passing between the heads of the second and third metatarsals it passed medially towards the line of the first metatarsal head. Excessive weight-bearing was the result, and the joint thereby affected (the first metatarso-phalangeal) suffered. The cartilage became thinned, the approximated bony surfaces were deformed and flattened, there were signs of osteo-arthritis in the shape of lipping of the joint edge, and periarticular fibrosis. The acquisition of a rigid joint was only a matter of time. In certain patients a still more distressing stage may develop, for the pain of the stiffening joint is responded to by contraction of the flexor brevis hallucis, and if this is permitted to continue it will result in a great toe fixed in plantar flexion—a hallux malleus—one of the most painful and crippling of foot errors.

It is to an underlying flat-foot that the majority of cases of hallux rigidus owe their origin, and it obvious how important is an appreciation of this point when the question of treatment comes to be considered.

Treatment of Hallux Rigidus.

What of the treatment? It is none too easy, and, paradoxically enough, in certain cases the most fruitful line of treatment is to secure complete fixation of the affected joint, for with this result pain at least disappears.

Here are some suggestions which may prove helpful. It is evident that correction of any *coincident* or *pre-existing* flat-foot is essential, and the usual steps are accordingly taken: the inside of the boot sole is raised by one-eighth of an inch, an efficient longitudinal arch support is fitted, the golosh is strengthened, the musculature of the foot is improved by exercises and massage, and it may be that the conjunction of these various measures, in so far as they restore the statics of the foot, will relieve the hallux rigidus. Raising the heel of the boot is sometimes helpful; it seems to diminish the pain, and it maintains the toe-joint in such a position of slight dorsiflexion as to increase the comfort of walking, even if fixation should occur.

It has been recommended that the joint should be freely moved under an anaesthetic and fixed in plaster in a dorsiflexed position for a few days, thereafter ensuring a course of free, active movements. My experience with this procedure has been disappointing, for it has seemed that in a certain proportion of cases it resulted in increased discomfort. I am coming to the conclusion that a better conservative measure is to encourage fixation in the toe, a condition secured in some measure by incorporating in the boot sole, immediately underneath the loose inner sole, a strip of thin steel or duralumin extending from the middle of the instep to the interphalangeal joint of the toe. It has been my experience, however, that conservative treatment is unsatisfactory, and that there is little prospect of improvement until operative intervention has been carried out.

Of the various operative procedures the best is that which entails removal of the base of the proximal phalanx and the tacking of a flap of fascia derived from the medial aspect of the toe over the raw surface of the bone. It is certainly unwise to remove the head of the metatarsal bone, for, if this is done to an extent required to correct the joint error, the stability of the longitudinal arch, and therefore of the foot, is seriously interfered with.

"MARCH FRACTURE."

My fifth case is of interest from the point of view of recognition of an injury which is easily overlooked. The patient had been on a walking tour carrying a heavy pack, and on the last day of his tour put in a walk of unusual length over rough ground. While he was on the last mile of his journey he experienced a sudden pain on the inner aspect of the foot immediately behind the heads of the first and second metatarsal bones. He imagined he had sprained the part; walking became a very painful affair, and shortly after the front portion of his foot became considerably swollen.

When he came under my care the signs were those of severe sprain with local tenderness behind the second metatarsal head; but an *x*-ray examination revealed the presence of what is termed a "march fracture"—a fracture of the second metatarsal bone at that narrow portion which lies immediately behind the head (Fig. 7). The second and third metatarsals are the bones most liable to be affected, and it is supposed that the liability is related to the blood supply. Repeated spasmodic contraction of the interosseous muscles interferes with the distal blood supply of the foot, so that there is an atrophy of the second and third metatarsals at their phalangeal extremities. The necks of these bones are naturally slender structures, and the influence upon the blood supply further increases the fragility, so that one or other yields under a strain which in ordinary circumstances would have been harmless.

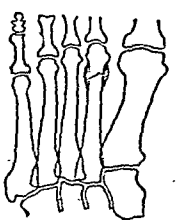

FIG. 7.—A "march fracture" sustained at the neck of the second metatarsal bone.

Once recognized, the treatment was easy. Fixation in plaster for three weeks was the plan adopted, but the importance of the case lies in the recognition of the possibility that in certain circumstances a fracture may occur in the course of such a simple exercise as walking.

"DANCING FRACTURE."

A somewhat similar experience illustrates my next case. The patient was dancing when she experienced on the *outer side* of her right foot a sharp pain, which she attributed to a kick from her partner. As the days went by the pain persisted and swelling appeared. What does

the radiogram reveal? There is a fracture at the base of the fifth metatarsal bone. (Fig. 8.) It is a mere chip off the base, and it has been produced, not by any direct violence, but by a sudden eversion of the foot and the pull of the peroneus brevis muscle. It is an example of what is appropriately called a "dancing fracture."

Here again the treatment consists in fixation of the foot until the fragment has reunited, and the interest is therefore not so much one of treatment as of the recognition of the fact that a fracture could have occurred in this somewhat indirect and oblique fashion.

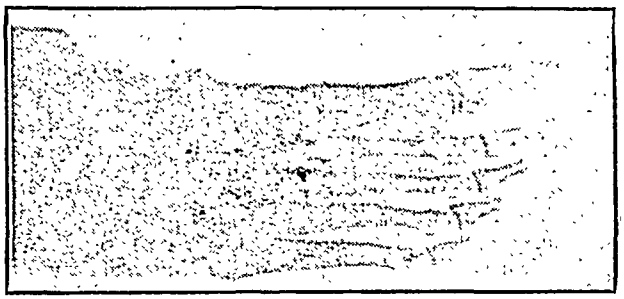

FIG. 8.—"Dancer's fracture" of the base of the fifth metatarsal bone, sustained by sudden eversion of the foot.

KÖHLER'S DISEASE.

Tarsal scaphoiditis, or Köhler's disease, is the subject of the next case. (Fig. 9.) A boy of 7 complains of discomfort on the inner border of the right foot, and there is an evident limp in walking. Examination reveals a swelling, apparently bony in source and occupying the position of the tarsal scaphoid bone. There was an indefinite history of a slight injury some months previously, which may or may not have a bearing upon this later development.

The condition gives rise to anxiety, and in the majority of cases fears are entertained that the condition is tuberculous. We have the comforting reflection that, whether specific treatment is adopted or not, the error passes on to spontaneous cure, leaving no trace of its existence except perhaps a predisposition to the development of flat-foot.

We know very little about Köhler's disease. It is in part a mystery why it should pick out the scaphoid. Three explanations have been put forward: (1) that the scaphoid is the last bone in the foot to ossify; (2) that, being the keystone of the arch, it is concerned with a great deal of weight-bearing; and (3) that it has a double or bilobed nucleus. While these may be predisposing influences in localizing the disease, we are by no means clear as to what constitutes the change. It is on a parallel with apophysitis of the heel bone, the Osgood-Schlatter's disease of the upper epiphysis of the tibia, and an unnamed condition of the crest of the ileum, similar in appearance and behaviour. The view generally held is that the condition proceeds from an obscure but distinctive infection, which, while not inducing pus formation, alters the texture of the bone and produces the irregular calcification distinctive of the condition. In some curious way it appears to pick out an epiphysis to which a tendon is attached.

FIG. 9.—Köhler's disease or tarsal scaphoiditis. The ossification of the scaphoid is reduced to a small central nucleus. The actual size of the bone is not appreciably diminished, but the cortical areas are decalcified.

No special treatment is required. Fixation of the foot may be an advantage, but it is not essential, and I think that the affection improves more readily if events are allowed to take their course.

SESAMOID BONES.

Accessory bones of the foot are sometimes a source of trouble and anxiety. An example of this is afforded by the following case. A man, aged 37, jumped from the top of a bank to the ground, a distance of three to four feet. There was a jar to the joint, and some pain around the ankle ensued. The condition was treated as a sprain, and no x-ray examination was at first carried out. Later, the symptoms proving intractable, an x-ray photograph was taken, but the rule of always x-raying both the affected and the healthy foot was neglected. The radiogram showed a segment of bone lying behind the astragalus, looking as though there had been a fracture of a small fragment from its posterior surface. But another radiogram, on this occasion of both feet, showed that the condition was bilateral. It was, in fact, an example of the os trigonum, a curious accessory bone of the foot which lies immediately posterior to the astragalus, and may easily be mistaken for the fragment of a fracture, particularly if there is a history of a compression injury to the bone. (Fig. 10.)

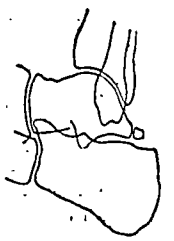

FIG. 10.—The os trigonum situated at the posterior border of the astragalus and giving an appearance liable to be confused with a fracture of the posterior extremity of the bone.

The existence of these accessory bones (sesamoids they actually are) should always be kept in mind. The most important examples are the ones I have just described—the os tibiale externum, and the peroneal sesamoid.

PATHOLOGICAL CONDITIONS OF THE HEEL.

There are certain conditions of the heel which are sometimes sources of difficulty in diagnosis. Let me briefly refer to them with illustrative cases.

Calcaneal Spur.

The first case is that of a man of 42, stout and heavy in build. He is a rheumatic subject, and this point is important in explaining the pathological condition. His complaint is intense pain on the under surface of the heel. It is chiefly noticeable when he puts weight upon the part, and may be agonizing in its intensity. On local examination there is little of importance to be seen, but pressure with a blunt point produces pain at one spot. An x-ray photograph established the condition as one of calcaneus spur or spine. (Fig. 11.)

FIG. 11.—Calcaneus spur developing in a man aged 46, and causing severe pain on the under aspect of the heel.

The origin of the condition is disputed, but it is generally believed to follow a slight tearing of the periosteum on the under surface of the os calcis resulting from a dragging on the attachment of the flexor brevis digitorum muscle. Other factors probably operate—for example, undue friability of the tissue—but the real origin is apparently a local periosteal tear in an individual whose periosteum

is the site of a mild infective process, such as we find in osteo-arthritis.

The problem of treatment is by no means easy. It would seem a minor and satisfactory procedure to remove the spur, but we have no guarantee that it will not re-form, and in a more extensive degree. When we recall that these spurs may disappear spontaneously, we feel that there is room for non-operative treatment. This takes the form of "protection." A thick felt is placed below the situation of the spine, a cup-shaped hollow ensuring freedom from pressure on the offending prominence. I am told that diathermy is of great value in hastening absorption of the deposit, but I cannot speak of this from personal experience.

Irregular Ossification of the Calcaneus.

The next two cases are examples of pain complained of at the back of the heel. The first patient is a 10-year-old schoolboy, in whom the pain first occurred after a long run. Since its onset it appears to have been produced by any undue amount of walking or running. It is described as an ache rather than a sharp pain, and with it there is often a cramp-like contraction of the muscles of the calf.

On examining the part two features are evident: the calcaneus is slightly broadened behind, while pressure over this area produces slight discomfort. An *x*-ray photograph shows that the metaphysis of the heel bone at the junction of the epiphysis and the body of the bone is the site of an intense but somewhat erratic activity. New bone is being formed in isolated clumps rather than in the uniform deposit of a healthy ossification; there is undue congestion, and the epiphysis itself shows the mottling of irregular ossification. (Fig. 12.) The appearances are those of a selective irritative process, probably toxic in character, though why it should exercise so local a selection is a mystery.

FIG. 12.—Apophysitis of the calcaneus in a boy aged 10. The epiphysis shows characteristic irregular ossification.

The condition need cause no alarm; it responds to counter-irritation, raising of the boot heel to relax the tendo Achillis, rest, and the elimination of any undue degree of local pressure.

Calcaneal Bursitis.

The other case in this group illustrates a different explanation of somewhat similar symptoms. The patient complains of pain over the back of the heel, with recurrent cramp of the calf muscles and the appearance from time to time of a tender swelling at the point from which the pain seems to originate. An *x*-ray examination yields negative results. On investigation it is found that there is an area of local tenderness over the upper part of the posterior aspect of the heel, and it may be possible to detect a localized swelling at the point of tenderness. The case is one of inflammation of the calcaneus bursa. The anatomical bursa lies between the tendo Achillis and the posterior surface of the calcaneus, but an adventitious bursa frequently arises in a subcutaneous position and immediately overlying the point of insertion of the tendon. Both bursae, but particularly the latter, are liable to irritation by ill-fitting shoes, and, if the overlying skin becomes blistered or broken, a lymphatic infection of the bursal space ensues.

Attention to the footwear may be all that is required to remedy the error, but, if a definite infection of the bursa is established, it is wiser to remove the sac under local anaesthesia and thereafter to take precautions against recurrence of the irritation.

PLACENTA PRAEVIA AND ITS RESULTING FOETAL MORTALITY.

BY

F. NEON REYNOLDS, F.R.C.S.ED.

IT appears from statistics that placenta praevia is found about once in every 500 cases, and is most common in women who have had many pregnancies, especially if these have occurred in rapid succession. Little is known of the etiology of the condition, but two theories have been put forward:

1. *The ovum may be implanted from the beginning in* the lower uterine segment and the placenta formed, as usual, from the decidua basalis. It is not known why the *ovum becomes attached to the lower segment; it may be due* to a deficiency in the ordinary properties of the chorionic villi or to some condition of the decidua, such as previous inflammatory changes, which render it unsuitable for implantation.

2. The ovum may be implanted in the upper segment in *the usual way, but the villi of the decidua capsularis pro*liferate instead of undergoing atrophy, and invade the decidua vera of the lower segment after contact has been *brought about by growth* of the ovum. Then proliferation of the villi of the decidua capsularis would form part of the placenta in the lower segment.

PATHOLOGY.

The placenta is usually larger, more degenerated, and contains more infarcts than normal. These changes may be accounted for by the fact that it can obtain only a comparatively poor blood supply. The cord often has its insertion at the margin. The lower segment and the cervix are generally thicker than usual and more vascular; they do not dilate as easily, and tear more readily. The haemorrhage, which is the chief symptom, comes from the maternal blood vessels, which are opened by the separation of the placenta when the cervix dilates. There is no foetal haemorrhage unless the placenta is torn by manipulation in treatment.

VARIETIES.

There are two varieties of placenta praevia: (1) Complete, in which the placenta entirely covers the internal os. (2) Incomplete, in which the placenta does not cover the os. Of this variety there are two types: (*a*) in which the placenta partly covers the internal os so that it can be felt by the examining finger through the os; (*b*) in which the placenta is situated in the lower uterine segment but does not come as low as the internal os, and therefore cannot be felt unless examination be made above this level.

The terms "central," "marginal," and "lateral" are also used to denote these three degrees. It must be remembered that a placenta which appears to be central when the os admits one finger may be marginal when the os is further dilated.

SYMPTOMS.

Haemorrhage is the only symptom, and usually takes place during the last four weeks of pregnancy; it may, however, occur at any stage. It is not necessarily accompanied by labour pains, being caused in some cases by painless contractions which open the os. The bleeding may start as small repeated losses or as a severe and alarming haemorrhage, but is always intermittent. There is sometimes a history of trauma or somewhat strenuous exercise, but commonly no apparent cause is present to determine the onset. There is no pain apart from possible labour pains, and on palpation no tenderness of the uterus is noticeable. Foetal parts are felt as usual, and there is no alteration in the normal tension of the uterus.

DIAGNOSIS.

The diagnosis may be considered in two stages: first, before there has been any haemorrhage, and secondly, after the onset of haemorrhage, the latter being the stage at which placenta praevia is usually diagnosed.

Before the Onset of Haemorrhage.

All cases of pregnancy should be examined particularly carefully during the last few weeks, as it is during this period that the abnormalities, such as placenta praevia, can be discovered or suspected. The signs which might excite suspicion of the presence of this condition are:

(1) *On abdominal examination*: (*a*) Abnormal lie of the foetus. There may be a transverse lie, or the head may be felt very high up, perhaps lying in one or the other iliac fossa. (*b*) An unusually loud souffle heard over the pubic region.

(2) *On vaginal examination*: Difficulty in reaching the presenting part or feeling it in one fornix but not in another, or failing to feel any presenting part at all. Inability to push the presenting part into the pelvis in spite of normal pelvic measurements, and the fact that the promontory of the sacrum cannot be felt, or that there have been previous confinements without trouble. The feeling of a soft, boggy mass filling all or part of the fornices. This, once experienced, is not likely to be confounded with a breech presentation or hydatidiform mole, in both of which conditions there are other definite guiding signs.

If the diagnosis can be made at this stage, or the condition be suspected, precautions can be taken and arrangements made to institute prompt treatment in what is one of the most serious complications of pregnancy.

After the Onset of Haemorrhage.

This resolves itself into the differential diagnosis of antepartum haemorrhage; we have to distinguish between placenta praevia and accidental haemorrhage. The only definite sign of a placenta praevia is feeling the placenta through the partially dilated os. In attempting to do this it must be remembered that the edge of an incomplete placenta praevia may be some distance from the os, and no case should be labelled as one of accidental haemorrhage without a thorough examination. In this connexion I would urge the use of an anaesthetic in all but those cases which can be examined without straining, and in which the placenta is felt immediately upon introducing the finger into the os. Under an anaesthetic the examination can be made carefully and completely with less risk of trauma, which would increase the haemorrhage, and less risk of introducing infection—a further consideration of very great importance. Supporting evidence will be found in those signs which have been mentioned under the heading of diagnosis before the onset of haemorrhage.

In accidental haemorrhage the foregoing evidence is lacking except in those rare cases in which placenta praevia and concealed accidental haemorrhage are present together. We must not be misled by the presence of blood clot in the vagina or cervix; this should be carefully cleared out, with the help of a douche if necessary, and further examination made. The bleeding in accidental haemorrhage is steady and continuous. In a case of mixed external and concealed accidental haemorrhage the presence of pain apart from uterine contractions, tenderness on palpation, and increased tension of the uterus, together with the general condition of the patient, are sufficient to distinguish the condition.

To summarize these points:

Placenta Praevia.	*Accidental Haemorrhage.*
No pain.	Pain (concealed variety).
Uterus flaccid except during contractions.	Uterus not relaxed between contractions (concealed).
Uterus not tender to palpation.	Uterus tender to palpation (concealed).
Haemorrhage intermittent.	Haemorrhage continuous.
Presenting part felt only partially or not at all.	Presenting part felt normally.
Placenta felt per vaginam.	No placenta felt per vaginam.
Malpresentations common.	Malpresentations not specially associated.
Not commonly associated with toxaemias.	Commonly associated with toxaemias.

Hydatidiform mole with haemorrhage, and in which the mole can be felt through the os, may be confused with placenta praevia. In this, however, we have to guide us the size of the uterus, which is greater than it should be for the supposed period of pregnancy, and the absence of any foetal parts. Two other conditions which must be borne in mind are bleeding from a cervical polypus or from a carcinoma of the cervix. Both of these are generally easily discovered if careful examination is made.

TREATMENT.

This is by far the most difficult problem presented by placenta praevia. Each case must be carefully examined in all detail, and no hard-and-fast rules can be laid down. Certain lines of treatment are open to us.

1. Leaving alone.
2. Rupturing the membranes.
3. Rupturing the membranes and plugging the vagina.
4. Version and bringing down a leg.
5. Insertion of a de Ribes's bag.
6. Caesarean section.

All these methods have as their object control of the haemorrhage and the safe delivery of the patient. Choice of them can only be made after a careful study of the following points.

Condition, age, and parity of the patient.
Type of placenta praevia to be dealt with.
Period of gestation and condition of the infant.
Stage of labour—that is, degree of dilatation when the diagnosis is made.
Conditions under which treatment has to be carried out.

If the patient is fit and not yet affected by loss of blood any of these methods may be considered; if, however, we have to deal with a shocked, exsanguinated patient, our first consideration must be to stop the haemorrhage and combat the shock by the quickest and most effective method which does not, in its performance, involve any added strain or exhaustion. The method of choice here is to rupture the membranes, plug the vagina, and apply a tight abdominal binder from above downwards. The shock can then be dealt with by the usual means, and later, when the patient has somewhat recovered, other treatment can be decided upon if necessary. In this connexion the value of blood transfusion, which often may be the measure determining recovery, must not be overlooked. The operation can easily be carried out in the patient's home with simple apparatus; a microscope is not necessary for testing the blood of the donor against that of the recipient, and a complete grouping of both need not be done.

Age and parity are important in the case of the elderly primipara, with little chance of further pregnancies, for whom a living child is very essential. Immediate Caesarean section is then indicated, except in the very mild, incomplete type of case requiring no active intervention. In a multipara with several living children, or a young primipara with plenty of time for further chances, the infant is generally disregarded and treatment directed solely in the interests of the mother. In considering the period of gestation and the condition of the child it is obvious that in a very premature labour, or if the child is already dead, the mother is again the only consideration.

The type of placenta praevia is important; in the complete or central type Caesarean section should always be performed, provided the child is alive. The nearer the approach to the lateral type the more effective will be the natural force of labour in controlling the haemorrhage.

The stage of labour—that is, the amount of dilatation of the os when the diagnosis is made—has a direct bearing upon the treatment, since the less the dilatation the more difficult and dangerous to the patient is any form of treatment involving manipulation through the os. Therefore, with a dilatation of less than two fingers, rupturing the membranes and plugging the vagina is generally indicated (subject to the other conditions being satisfied), even if only as a preliminary to other procedures. With a dilatation of two fingers or upwards there is the choice of version and pulling down a leg or the insertion of a de Ribes's bag.

The question of the conditions under which treatment is to be carried out is one upon which there can be very little difference of opinion. Every case of placenta praevia, unless so slight that no treatment, beyond perhaps simple rupture of the membranes, is required, should be treated in hospital or a nursing home unless the patient's home allows facilities equal to those afforded by such institutions. The most difficult and important part of any form

of treatment is the prevention of sepsis; such undertakings as plugging the uterus cannot be carried out efficiently and with a minimum risk of subsequent sepsis unless conditions conform to a standard which is seldom available in patients' homes.

Having considered these factors which guide us in the choice of treatment we can now take the individual methods and see in what type of case each one is indicated. We can leave alone the very slight case with an occasional small haemorrhage, provided that the labour is not prolonged sufficiently for the patient to be affected by the repeated slight losses. Many such cases are diagnosed as accidental haemorrhage, but it is more probable that they are due to a low placenta.

Rupturing the membranes is sufficient in the milder cases of the lateral type in which labour has begun, and also in those cases in which there is no serious loss until the os is more than half dilated. If the membranes are then ruptured the presenting part can be pushed well down and a binder applied with good control of the haemorrhage. It must be remembered that rupturing the membranes is *not a reliable* method of inducing labour, and for that reason should not be used alone in the absence of good uterine contraction.

Rupturing the membranes, plugging the vagina, and applying a tighter binder is indicated in the incomplete type of moderate severity with dilatation of less than two fingers, in cases in which labour has not begun, and in all cases in which the condition of the patient, from shock and loss of blood, is too bad to admit of any more extensive treatment. It must be remembered that, to be effective, the plugging must be carried out very carefully, if possible under an anaesthetic and with the aid of a speculum; it must start well back, and care must be taken that the plugging is placed behind the cervix to start with, and does not merely push the cervix backwards. If not carried out efficiently haemorrhage will continue above the plug. The danger of sepsis following this procedure cannot be too strongly emphasized, and the plug should always be removed as soon as possible. This method should, in fact, be looked upon only as a preliminary to other treatment in the severe cases, or as a means of inducing uterine contractions.

Version and pulling down a leg is a sure and fairly safe method of immediately controlling the haemorrhage in cases of the incomplete type with severe bleeding, or in the central type seen too late for Caesarean section. It almost invariably results in good contractions and subsequent delivery without further intervention. It is always indicated in the case of a small or premature foetus with a vertex presentation and in transverse lies. Breech presentation should be treated by bringing down a leg. Version should always be by the external method where possible; this will give a minimum of trauma and of risk of sepsis. Once the breech is down, a leg can be seized with very little manipulation. It should not be persisted in if found very difficult, and should never be carried out if there is any disparity in size between foetal head and pelvis.

De Ribes's bag can be used instead of the half-breech; it can be introduced with less dilatation than is required for pulling down a leg; it is effective in controlling the haemorrhage, and gives a better chance of a living child. There are, however, very definite disadvantages. It is not such a good stimulus to labour, and it may dilate the os without producing labour pains, especially if traction is used. Thus there is considerable risk of a severe and sudden haemorrhage when the bag is expelled into the vagina. This will necessitate further procedure to get the presenting part down in order to maintain controlling pressure. The presenting part may be displaced by the bag and an oblique lie result; the bag perishes easily, is not always available in an emergency, and is a ready means of introducing sepsis.

One other method of this type must be mentioned—namely, traction from Willet's forceps applied to the foetal scalp. Good results have been obtained, and it causes surprisingly little damage to the child other than a cephalhaematoma.

Caesarean Section.

The use of Caesarean section in placenta praevia is a much-discussed question, and one upon which unanimity of opinion is seldom found. Certain cases, however, definitely require this method of treatment.

1. All cases of the complete, or central, type if the condition of the mother allows it.

2. Cases in which the birth of a living child is of great importance—for example, in elderly primiparae.

3. Cases in which there is any mechanical obstruction to delivery, such as a rigid cervix or disproportion between the size of the child's head and the pelvis, however slight. (It can be understood that the extra difficulty produced by such complications might be just too much for a patient who has undergone a somewhat prolonged labour and is weakened by loss of blood.)

4. Cases complicated by toxaemia or constitutional conditions, such as cardiac disease, which require the labour to be as short and as easy as possible.

5. Cases of twin pregnancy.

In considering this method of treatment the conditions under which it has to be applied are all-important. Carried out in suitable surroundings by one accustomed to the operation it has the advantage of being a fairly safe means of terminating a condition which seriously threatens the life of the mother; also it gives the best chance of a living child, and its performance is not affected by such conditions as an abnormally large child or comparative pelvic contraction, which increase the difficulties of the other methods. The disadvantage lies chiefly in the potential weakness of the uterine scar and its behaviour in subsequent pregnancies. This is a point to which I shall refer *again later*.

Dangers of Placenta Praevia.

There are certain dangers which have to be faced in placenta praevia no matter which particular treatment is used.

1. *Post-partum Haemorrhage from the Lower Uterine Segment.*—This is due to the relatively poor power of contraction possessed by the lower segment, and the consequent failure to occlude the large sinuses opened up by the separation of the placenta. This haemorrhage must be treated by the usual means, such as compression, packing, and drugs. It may be necessary, in cases in which Caesarean section has been performed, to remove the uterus, but this is generally only called for when the whole uterus is soft and flabby, and cannot be made to contract. Treatment of such a case by Caesarean section facilitates control of the haemorrhage, as with the abdomen open direct pressure can be applied and the uterine arteries compressed.

2. *Rupture of the Lower Segment.*—In normal cases the lower segment is much thinner, more friable, and less elastic than the upper, and this is still more marked at the site of implantation of the placenta. For this reason all manipulations must be carried out with the greatest possible care, especially such procedures as version or the application of forceps, which may be necessary after the expulsion of a de Ribes's bag. It is an accident which is very sudden in occurrence, and is almost always fatal.

3. *Sepsis.*—The placental site is close to the vagina, which is never sterile; it is therefore very easily infected during examination or manipulations, or subsequently during the puerperium. In addition, the resistance of the patient is lowered in proportion to the amount of blood which has been lost.

Prognosis.

The outlook for the mother depends very largely upon how soon the diagnosis is made. Many fatalities are due to the occurrence of severe haemorrhage, or to the introduction of sepsis before the true condition is appreciated and efficient treatment instituted. In arriving at a prognosis the presence or absence of uterine contractions must be considered. A well-contracting uterus means a healthy one, not yet weakened by excessive loss of blood, and is

an indication that the patient is still in a fair condition to withstand the severe demands to be made upon her.

The cause of death is haemorrhage, either ante-partum or post-partum, shock from manipulation or instrumental delivery, sepsis, or such tragic accidents as rupture of the lower segment or pulmonary embolism, the last of which is, perhaps, specially liable to occur in this condition. The maternal mortality may be taken as about 5 to 6 per cent. The figure given by Queen Charlotte's Hospital[1] in a series of 308 cases is 5.5 per cent., taking all methods of treatment together. It is interesting to look at the results of the individual methods.

	Cases.	Per cent.
Spontaneous delivery	62	6.4
Vaginal plugging	53	1.9
De Ribes's bag	38	7.9
Version and bringing down a leg ...	101	6.0
Caesarean section	54	5.5

From this it will be seen that the lowest mortality is from vaginal plugging; but it must be remembered that this method is sufficient only in the treatment of the milder cases of the lateral type, especially those in which haemorrhage is controlled with the onset of labour. The next lowest is from Caesarean section, the method used in cases of the central type.

The outlook for the child is uniformly bad; a large number are stillborn, and many die shortly after birth. The causes of death are asphyxia from placenta separation, haemorrhage from laceration of the placenta, pressure on the cord, and prematurity. The figure from the series of Queen Charlotte's Hospital is 59 per cent. Taking the different methods individually we get:

Spontaneous delivery	43.5 per cent.
Vaginal plugging	58.5 "
De Ribes's bag	57.0 "
Version and bringing down a leg	78.0 "
Caesarean section	42.6 "

Version and bringing down a leg, which was decided upon in this series 101 times—nearly twice as often as any other method—gives the appalling foetal mortality of 78 per cent. It appears from this large series of cases, which may be taken as fairly representative of present-day results, that in the commonest type of placenta praevia, under up-to-date treatment, we get a maternal mortality of 6 per cent. and a foetal mortality of 78 per cent.

I have given an outline of what appear to be the generally accepted views upon the treatment of this condition. These views, in spite of occasional sporadic and individual criticisms and many discussions, have been held for many years, and there has been very little improvement in results. The general feeling among obstetricians is one of dissatisfaction. No one should be satisfied with a foetal mortality of nearly 80 per cent. I can think of no other condition in which this figure is even approached. It is true that the mother must always be the first consideration, but equally the child does or should matter. A treatment is required which lowers the foetal mortality and at the same time decreases, or at all events does not increase, the maternal mortality.

I should like to make a plea for the wider use of Caesarean section in those cases of placenta praevia which would otherwise require plugging, version, or a de Ribes's bag. It is certain that, provided the diagnosis be made sufficiently early, this method would considerably diminish the foetal mortality without detriment to the chances of the mother. Many men of repute have put forward the same plea, but without success.

Blair Bell[2] in 1920 said: "I am certain that Caesarean section is the proper treatment in a large majority of cases. . . . I am, indeed, convinced that Caesarean section affords no more danger to the mother than version and delivery per vias naturales. Those who still hold to version as the treatment of election must therefore justify their indifference to the fate of the child."

Herbert Spencer[3] considered that Caesarean section was rarely indicated, and gave as his reasons that after version the mother could have children with safety, which was not the case after Caesarean section, and that the child, owing to its prematurity, would often succumb. This second objection can surely be dismissed at once; no one would advocate this treatment, except on very special grounds, in a case in which the child was so premature as to make its survival a matter of doubt.

Jellett,[4] in 1925, made a vigorous reply to a plea for Caesarean section put forward by Watson and Miller.[5] He cited a low maternal death rate, under 5 per cent., and referred to the fact that treatment had not altered for nearly thirty years, suggesting that this was due to the generally satisfactory results obtained. He completely ignored the child's claim for consideration.

Let us now see what are the disadvantages and dangers of Caesarean section. At the time of operation the condition of the patient must be taken into account, together with the risk of haemorrhage and sepsis, all of which are also serious considerations in any other method. If the diagnosis can be made sufficiently early there is less shock, less risk of haemorrhage or sepsis in Caesarean section than in any other form of treatment. It is, however, to the later effects that Spencer was referring when he said that the mother could not usually have subsequent children in safety. The general mortality of the operation performed under suitable conditions and not in extreme emergency is probably not higher than 2 or 3 per cent., so that from this point of view the maternal mortality would not be increased. The danger of the rupture of the uterine scar in subsequent pregnancies is the most grave objection to be considered. Eardley Holland, who in 1920 made a thorough investigation into this question, gives 4 per cent. as the frequency of rupture of the scar. Other figures are those of Munro Kerr[6] 1.8 per cent., and Couvelaire[7] 2 per cent. We can, however, take the conclusions come to by Eardley Holland[8] upon the largest number of cases ever investigated in this connexion to prove that this risk can be reduced. The cause of ruptured scar is imperfect healing leading to a thin scar, in which muscular union has failed. Factors leading to this imperfect healing are infection of the uterine wound and unsuitable methods and material in suturing the uterine incison. Eardley Holland found that the incidence of rupture was far greater when catgut was used to suture the uterus than when the suture material was silk or silkworm-gut, and he advocates the regular use of the latter material.

The operation is not difficult, but it is too often carried out in an atmosphere of hurry. Remarks to the effect that the whole operation took only twelve minutes should be regarded as inviting criticism rather than congratulation. There is no need for any undue haste, especially after the child has been delivered; very rare indeed are the cases in which an extra few minutes will affect the patient adversely, and the utilization of those few minutes in obtaining good contraction of the uterus and careful, accurate suturing will be amply repaid by the results, both immediate and remote. In the light of modern knowledge, with improved methods and material, and with more regard to the technique of asepsis, the risk of rupture of the uterine scar can surely be very considerably reduced.

Conclusions.

1. The question of foetal mortality in placenta praevia is worthy of serious consideration.

2. Wider use of Caesarean section can reduce this mortality without increasing the risk to the mother.

3. This method has never been tried upon a sufficient number of suitably selected cases for a correct estimate of its value to be made.

4. The usual objections to this method of treatment can be largely discounted when the operation is performed by the modern technique and under suitable conditions.

AN INVESTIGATION OF THE END-RESULTS OF COLLES'S FRACTURES.

BY

E. D. GRASBY, M.B., B.S., AND S.-R. TRICK, M.B., B.S.,

LATE HOUSE-SURGEONS, GUY'S HOSPITAL.

THE following account is based on the examination of about 50 cases of Colles's fracture sustained at least two years previous to our examination, in an endeavour to ascertain the causes for the imperfect results that obtain from the usual methods of treatment at present adopted. Our investigation was made on different lines from those of Edwards and Clayton, whose interesting analysis of 424 fractures of the lower end of the radius in adults appears in the *British Medical Journal* for January 12th (p. 61), but we feel that this account may be of value, particularly when compared with theirs.

In each case investigated the original *x*-ray plates were obtained when possible and the out-patient card traced. On re-examination the following observations were made: (1) Range of movement compared with the uninjured wrist. (2) Localized areas of tenderness. (3) Symptoms complained of by the patient. (4) Deformity. (5) Functional result—patient's own opinion.

The accompanying table, indicating the results in the first 20 cases, is quite typical.

Table showing the End-results in Twenty Cases of Colles's Fracture Treated by the Usual Methods.

E. J.	– N.R.	60	70	75	75	–	–	–	Good.

Disp. of orig. fract. = Displacement of original fracture. N.R. = No reduction. R.G. = Reduced with gas. In columns 3 and 4, F. = Fractured, and N. = Uninjured wrist. Ost. arthr. inf. R.U. jt. = Osteo-arthritis in inferior radio-ulnar joint. Radial dev. = Radial deviation.

From this table it is seen that the results were good in 60 per cent. of cases, fair in 15 per cent., poor in 5 per cent., and bad in 20 per cent. The proportion of good results (60 per cent.) would appear quite satisfactory, but it is interesting to compare those fractures in which there was little or no displacement with those in which displacement was a marked feature; thus:

Without displacement	12=60 per cent.
With displacement	8=40 „

It is seen, therefore, that, as would be expected, uniformly good results obtain where no displacement had occurred, but of the remaining cases 50 per cent. are bad, 12½ per cent. poor, and 37½ per cent. fair.

From our investigation it would appear that the results of Colles's fractures with any displacement will in two years be bad in half the cases and unsatisfactory in the remainder. In our series not one result could be described as good, the majority were thoroughly bad.

It is reasonably assumed, where existing displacement of the fragments of a fracture has been reduced and good anatomical apposition restored, that, provided no comminution has occurred, the functional result would be satisfactory, in the same way that a simple fracture without displacement provides a perfect functional result. Our attention was therefore directed to this factor—incomplete or imperfect reduction—as a predisposing cause of bad results.

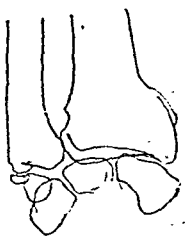

FIG. 1.—Old Colles's fracture with marked radial deviation and displacement. Ununited fracture of the styloid process of the ulna.

In case A. H., the fourth in our series, the apparent displacements of the distal radial fragment are (1) backward rotation, (2) radial deviation and rotation. The effect of these displacements is manifest in the inferior radio-ulnar joint, which becomes the seat of marked osteo-arthritis. It will be observed that the articular surfaces are at an angle as seen in the antero-posterior view (Fig. 1), and are markedly out of alignment in the lateral plane. The case of S. W., the eighteenth in our series, was identical, and showed marked unreduced radial deviation with consequent arthritis. Both of these patients were unable to use their wrists or perform any manual work;

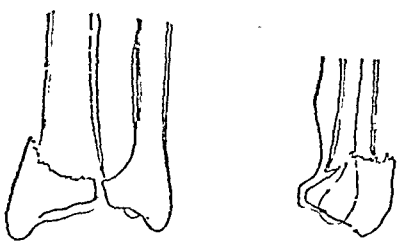

FIG. 2.—Case of S. W. Tracings of *x*-ray photographs taken at time of injury (August 19th, 1924), showing uncorrected radial displacement and backward displacement.

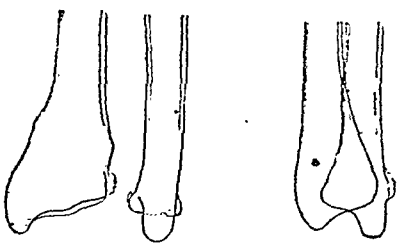

FIG. 3.—Case of S. W. Tracings of *x*-ray photographs taken November 17th, 1926, more than two years later, showing radial displacement and backward rotation of distal radial fragment. Advanced osteo-arthritis in radio-ulnar joint.

they represent the most unsatisfactory result of inadequate treatment and imperfect reduction. In every bad case it was possible to demonstrate osteo-arthritis by *x*-ray examination as in these two cases, and care was taken to exclude those in whom generalized arthritis was present in other joints.

Tracings of the plates of S. W. taken on August 19th, 1924, are reproduced for comparison with those of November 17th, 1926 (Figs. 2 and 3), and it is seen that (1) the radial displacement has not been reduced; (2) the backward rotation has been reduced without previous disimpaction, with the result that the backward displacement persists. It will be seen that the backward rotation is,

however, still present in the x-ray photographs taken on November 17th, 1926, showing that disimpaction must be obtained before any attempt at reduction is made, and that immobilization was not sufficiently prolonged.

The concomitant fracture of the styloid process of the ulna, so frequently seen in association with Colles's fracture, remains ununited in approximately 50 per cent. of cases; but it was found in this investigation that, contrary to the usual teaching, no symptoms or pain arise from this injury in the event of non-union. No case in our series exhibited symptoms that could be definitely attributed to non-union of the ulnar styloid, and we agree with Edwards and Clayton that fracture of this bone makes no difference to the end-result.

From this early review of our results (our investigation is not complete) the causes of imperfect function of the wrist after a Colles's fracture would appear to be (1) backward rotation of the distal radial fragment; (2) radial deviation and displacement of the distal radial fragment. As the most usual complaint was of pain, it was found difficult to decide how much disability could be attributed to weakness of the wrist due to loss of mechanical efficiency of the flexor tendons when the backward tilting of the radial fragment is uncorrected. In most cases the pain from arthritis in the inferior radio-ulnar joint was sufficient to render the wrist useless and "apparently" weak, but in all cases it was possible to demonstrate well-marked arthritis where the fragments had not been restored to perfect anatomical apposition. For this reason, whatever the immediate result of treatment, the most important cause of bad results would appear to be osteo-arthritis ensuing as an ultimate sequel to imperfect anatomical restoration of the fragments, and this necessitates reduction of both the backward displacement and the radial deviation and displacement.

TREATMENT.

In undertaking the treatment of Colles's fractures every effort should be made to restore complete anatomical position of the fragments, which we believe can only be obtained by complete disimpaction of the fragments before manipulation and by immobilization for a longer period than at present advised.

Choice of Anaesthetic.—Although the majority of cases are reduced under gas anaesthesia, complete relaxation is seldom obtained, and when possible a general anaesthetic is very much to be preferred. We feel that many imperfect results follow the rapid, incomplete manipulation necessitated by a short "gas" anaesthetic.

Manipulation.—Complete disimpaction of the fragments is essential before any attempt at manipulation is made. The method advocated by Sir Robert Jones is adopted, and manipulation is continued until free movement is permissible between the fragments. Reduction of the deformity is then obtained, with restoration of the true anatomical apposition. It is at this stage that a general anaesthetic is preferable to gas, as adequate time can then be taken for the application of the splints—a most important part of the treatment. It is possible to obtain an excellent reduction of the fracture with short anaesthesia, but if the patient commences to struggle before the splints have been applied—a frequent occurrence with gas anaesthesia—the deformity may readily be reproduced, or the operator contents himself with a "satisfactory" instead of a "perfect" reduction.

Splints.—The diversity of splints that have appeared for the treatment of this particular fracture testifies to the difficulty in obtaining a really satisfactory splint which will suit every case. Carr's splint is almost universally adopted as the routine splint, but is not suitable for every case. The practice of maintaining the wrist in a fully flexed position for twenty-four hours we believe to be unsatisfactory, and does not fulfil the important function of keeping the fragments in position, as has been claimed for it. The many special splints invented are too expensive and complex for routine treatment. Since commencing this study we have made use of two common splints—the anterior angular splint in conjunction with a straight back splint, both made of wood, simple in construction, and usually readily obtained. This method of splinting Colles's fractures is similar to that described by Scudder, but we prefer an anterior angular splint to the straight splint he uses. It is, of course, too early to be dogmatic about this method of treatment, but our results have been encouraging enough to prompt us to offer the method as a suggestion for others who may adopt it and give it a trial. We claim no originality, as the method is fully described by Scudder; rather we would revive this simple and efficient method, which is as follows:

An anterior angular splint is chosen so that when lightly padded it will extend to the ball of the thumb. The straight posterior splint should be long enough to extend from the elbow to the metacarpo-phalangeal joint. Each splint is padded separately for each case with a single layer of wool, and in the posterior splint a pad of wool is placed so that it will rest immediately below the distal radial fragment. The anterior splint is similarly stuffed with a pad of wool placed so that it will rest opposite the lower end of the proximal radial fragment, and, in addition, is padded so that it will fit the

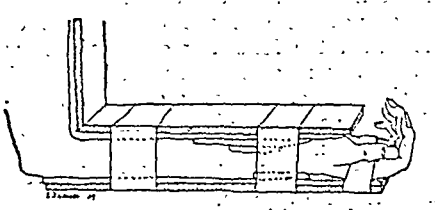

FIG. 4.—Diagram illustrating method of application of splints and strapping in suggested form of treatment for Colles's fracture.

contour of the front of the forearm. It is to be noticed that the back of the forearm is quite straight when the forearm is supinated. The posterior splint is applied first with the forearm supinated, and the anterior splint follows, the fracture being as it were squeezed between the splints. Three strips of strapping are next applied, the first round both splints immediately over the fracture, the second in front of the elbow, also around both splints, and the third across the palm of the hand, fixing the hand to the posterior splint but allowing free movements of the fingers. The strapping should not be applied too tightly on account of the subsequent swelling which invariably occurs, and when applied pressing the splints together should render them slack. The forearm is then fully supinated and the whole firmly bandaged. By this means the fragments are securely immobilized and a good position maintained, and the fingers are free to commence active movements from the first. In addition, the hand may be fixed in adduction to overcome the radial deviation by the third piece of strapping. The arm is supported in a sling. The patient is seen the next day, and if there is any swelling the splints are carefully reapplied, the patient being encouraged to move the fingers as much as possible. The splints are not removed permanently for a week, after which massage and gentle movements are instituted, but this period between the injury and the commencement of massage will vary with individual cases. The advantages of this method are that the splints are comfortable in spite of the position of supination, and the position of the fragments is maintained, also that the method can be applied to every case, including the severely comminuted fracture and T-shaped fractures, both of which seem to do well when immobilized in supination.

CONCLUSIONS.

1. Colles's fractures without displacement yield uniformly good results, as observed two years after the injury.

2. Where displacement was a marked feature of the fracture the results two years after the injury are invariably unsatisfactory.

3. The disability was in each case due to osteo-arthritis in the inferior radio-ulnar joint, resulting from incomplete reduction of the fracture.

4. Non-union of the fractured ulnar styloid process does not affect the functional result.

5. Emphasis is laid upon restoration of anatomical apposition as important in the treatment, and a method of splinting is suggested.

We wish to thank Mr. E. G. Slesinger for permission to make use of the records of the fracture department of Guy's Hospital for this investigation, and for his kindly interest and helpful suggestions.

APHONIA AND HOARSENESS.*

BY

C. A. SCOTT RIDOUT, M.S., F.R.C.S.

I PROPOSE to make some observations on aphonia and hoarseness arising acutely. All of us are familiar with the sudden aphonia in a child or adult who has contracted a common cold associated with laryngitis; or with the croupy hoarseness, sometimes manifested instead, which generally yields to simple remedies. Now and again, however, especially in certain epidemics of so-called influenza, we come across cases not so simple in type which are associated with considerable oedema of the fauces and pharynx. In some of these cases oedema spreads to the arytenoids, which become so swollen as to resemble almost a pair of nasal polypi; the symptoms may become alarming and the aphonia may be associated with definite dyspnoea. The condition may be severe enough to necessitate laryngotomy or tracheotomy, though, as a rule, it yields rapidly to local scarification with a laryngeal knife. Should, however, the patient's condition then be too severe to permit of the necessary manipulation, laryngotomy must be performed at once. It is dangerous to impose on the heart, already toxic from the general infection, the strain of a battle against laryngeal obstruction, once this is producing a rising pulse, recession, and duskiness. At this point, furthermore, one might mention the possibility of an unsuspected diphtherial infection and urge that, however desperate the case may seem, tracheotomy may be performed just in time to save life. A few years ago I was asked by a medical friend to come at once and see a lad who was desperately ill with some respiratory obstruction so extreme that my friend did not think I would suggest doing anything. I found a lad of about 8 years of age, voiceless, livid, gasping, with marked recession of chest and neck, a feeble rapid pulse, and obviously in the last stages of laryngeal obstruction. Immediate tracheotomy at once changed the picture, and on investigation several of his school-mates were found to be carriers of diphtherial infection.

Simple Acute Aphonia.

Simple acute aphonia may persist when other signs and symptoms have passed off. The patient is generally a female aged 15 to 35; her cords are pearly white, perhaps slightly coated with mucus, but they do not approximate well; otherwise the patient is quite fit. I always hesitate to call a condition hysterical or neurotic on one examination, but if the patient, as often happens, can be made to say "E" quite well when the tongue is held out and the laryngeal mirror applied to the palate, or can be made to sing the vowels, the presumption is that the case is one of hysterical aphonia. It is necessary, however, to have repeated examinations until the patient has recovered, though as the patient has literally forgotten how to talk, this may take some time. Encouragement, suggestion, valerian, and faradism generally relieve the symptoms.

The aphonia, however, may not pass off so satisfactorily, and careful re-examination after two or three weeks is then essential. In this type of case the cords remain red or pink, slightly roughened or even granular, or the reddening may be unilateral without definite ulceration or swelling. The diagnosis of such cases presents perplexing problems, as the following will show:

A man of late middle age had what his doctor thought was an influenzal attack followed by hoarseness and loss of voice. On examination I found definite injection of the right vocal cord, with a little on the left; there was no loss of movement and no ulceration. I prescribed rest to the voice and steaming, but when I saw the patient again a week or ten days later the picture had changed. The right cord was now covered with pinkish granulations, the left was practically clear, but movements were still unimpaired. In the absence of chest signs I was still of opinion that the condition was post-influenzal, and probably of streptococcal origin. It was, however, thought expedient to obtain a further opinion, so we sent him to a leading laryngologist, who thought that the condition was either tubercle or early carcinoma, and advised punching out a portion of the cord for pathological examination. This operation the patient refused, and as he has since been perfectly well I believe that the original diagnosis was probably correct.

Streptococcal Laryngitis.

Other cases, however, do not end so happily. There are some with the same sort of history, but on examination a little shallow irregularity is noticed in the posterior half of either cord, perhaps very limited in extent and looking like a mouse nibble. The rest of the larynx may be slightly congested or the epiglottis may be very pale; there may be no arytenoid swelling, and movements may appear good. Alternatively the irregularity may take the form of a small definite ulceration with marked surrounding inflammation. Perhaps in the first variety careful examination of the chest will reveal pulmonary lesions, and a swab from the larynx itself show the presence of tubercle bacilli. In the second variety one may find only streptococci, though again pulmonary crepitations may be present. Even in the absence of tubercle bacilli one cannot say definitely that the case is not one of tuberculosis, though there are undoubtedly cases of streptococcal laryngitis with ulceration and even streptococcal pulmonary lesions, which simulate tubercle, especially among children. In any case treatment should follow a definite course: absolute silence must be enjoined, septic foci, such as carious teeth, septic tonsils and adenoids, removed, infected nasal sinuses cleansed, and if the swab shows chiefly streptococci, a polyvalent anti-streptococcal serum administered.

In a discussion on the question of oral sepsis in relation to lung conditions at the Royal Society of Medicine in January, 1928, I attempted to show by means of a series of cases the great improvement that might be brought about by removal of naso-oral sepsis, especially in children with pulmonary symptoms. One frequently meets cases of repeated attacks of laryngitis in children and adults in which the cause would seem to lie in a tonsil or sinus from which pus flows into the pharnyx and so to the larynx when the patient assumes the recumbent posture at night, and which clear up when the cause is removed. In advanced cases of laryngeal tuberculosis the outlook is desperate, but in one patient in whom the laryngeal condition was much worse than the pulmonary, tracheotomy, by insuring complete vocal rest, effected a cure.

Foreign Body in the Larynx.

So far I have dealt with aphonia and hoarseness apparently arising acutely, and gradually merging into chronic or intermittent forms. Before passing to the really chronic type I would, however, note that in sudden acute aphonia or raucous hoarseness the possibility of a foreign body must not be overlooked.

Many years ago, when I was doing a house appointment, a patient was admitted with a history of aphonia, which followed a violent spasm of coughing, brought on by swallowing a single tooth with a small plate and hook. Examination by indirect laryngoscopy showed the tooth balanced by its hook between the vocal cords, the hook being stuck on the upper surface of the left cord. This was in 1902, and as direct laryngoscopy was then unknown at the hospital an attempt was made to remove the tooth with a pair of laryngeal forceps. As this procedure only caused violent coughing, the patient was sent to the operating theatre for thyrotomy, but administration of the anaesthetic provoked a paroxysm of coughing and expulsion of the tooth.

About four years ago an 11 months infant was brought to me with a history of recurring raucous bronchitis with croupy cough. In the momentary view I was able to obtain by means of indirect laryngoscopy I saw something bright; I suggested a foreign body, and the desirability of administering an anaesthetic. Direct laryngoscopy through Irwin Moore's bronchoscope revealed a safety-pin caught in the right sinus pyriformis alongside the glottis. As the history was of four months' duration there is no doubt that the foreign body had been sucked in, and remained there during that long period.

Excessive Use of Voice.

Excessive use of the voice, common in newspaper boys, badly trained elocutionists, parsons, singers, etc., may manifest itself in permanently thickened congested vocal cords. One is often asked to tide over a difficult period—for example, Easter week—a parson whose voice is failing

* A paper read before the Winchester Division of the British Medical Association, November 21st, 1928

through excessive use or faulty production. It is only fair to warn the patient that further speaking may result in permanent damage to his voice; but if, as generally happens, he decides to carry on, then the best treatment one can suggest is that before speaking the patient should spray the throat with a 1 or 2 per cent. cocaine spray, following this, immediately he has finished, by steaming with menthol or friar's balsam. He may be given a sedative lozenge containing menthol, carbolic, and a little cocaine to suck intermittently, a medicine of strychnine and phosphoric acid to take internally, and advised to swallow a raw egg just before he is to use his voice. When the stress is over one orders complete vocal rest, attends to the condition of the nose, throat, and teeth, and gives advice on the subject of voice production.

The formation of singer's nodules is often accompanied by rapid failure of the patient's voice, or after a while its complete disappearance. These little nodules, whose site is at the junction of the middle and anterior thirds of the vocal cords, are best treated by rest, assisted if possible by cauterization with a pointed electro-cautery—not an easy manœuvre, but in most cases effective. In addition, of course, examination and treatment of conditions in the nose, nasopharynx, and tonsils may be required. These growths tend to disappear spontaneously, and should not be over-treated, though any septic causes should be removed. In adults I have found cauterization a satisfactory procedure.

Papillomata of the Larynx.

Another fairly common cause of aphonia in children and in adults below middle age are papillomata.

A boy of about 6 was brought to me because he could never talk above a low whisper. His condition had several times been diagnosed as laryngitis. On listening to his breathing I heard at every expiration a click, as though something were being driven against the glottis, and this suggested the diagnosis of papilloma. This diagnosis was confirmed by laryngoscopy, which revealed a stalked papilloma attached to the left vocal cord near the anterior commissure.

Only this year a boy aged 3 was sent to me on account of aphonia with some dyspnoea. During examination under an anaesthetic his condition became so bad that tracheotomy had to be performed, and on direct laryngoscopy a broad sessile papilloma was seen covering almost the whole of the glottis and attached to the right vocal cord. This papilloma was picked off piecemeal, the tracheotomy tube being left in for some weeks and then removed. After a few months the growth recurred and the same procedure had to be adopted again, but this time the tube was left in for several months. We are now trying to see what will happen if the tracheotomy wound is allowed to close.

Such cases may take years to get well, but it is quite certain that in children they must not be treated by laryngo-fissure, as this operation may be followed by permanent stricture of the glottis. Intralaryngeal methods and rest by tracheotomy are the treatment. In older patients one may meet a condition of multiple papillomata. In still older patients with recurring papillomata one fears the onset of malignant changes. These occurred in a patient who, after having papillomata removed at intervals of years from the true cords, had to have total laryngectomy performed.

Cancer of the Larynx.

Another variety of aphonia is illustrated in the type of patient, usually middle-aged or older, who complains of increasing hoarseness, probably suffers no pain, and attributes his symptoms to a cold. Examination of the neck reveals no growth or other abnormality, but there is often present advanced oral sepsis. In such cases careful laryngeal examination, if possible after oral sepsis has been treated, is vital, because commonly the cause of the hoarseness is a malignant growth involving a vocal cord or a superior ventricular band or spreading to these structures from the sinus pyriformis. Generally speaking, however, in the latter case there is accompanying pain on swallowing. At the present time I have under my care two cases of the type just described, with symptoms dating back six and nine months respectively. They both present almost inoperable carcinomatous ulceration involving the entire half of the larynx and reaching to the epiglottis.

Intrinsic carcinoma of the larynx, if caught early, is a curable condition.

A retired naval officer was sent to me in 1923 for slight aphonia, of which he had only complained a week or two. Examination showed a growth about the size of a pin's head attached to the under surface of the right vocal cord, the cord itself being freely movable. A portion of the growth punched off for examination proved to be typical carcinoma. I removed the right vocal cord and a small portion of the anterior end of the left cord with their surrounding tissues by window resection of the right ala of the thyroid cartilage, and rapid recovery with formation of scar tissue occurred. After about fifteen months a small pin's head nodule appeared on the middle third of the left cord, and this proved again to be a carcinoma. I performed a similar operation, removing, however, the arytenoid cartilage as well as the whole of the left cord, and uninterrupted recovery occurred. I believe the patient is still perfectly well.

Only early operation prevented this case from running the same course as the two previous ones. I have seen a case of urgent hoarseness with dyspnoea treated for five months as laryngitis, in which the growth had made such rapid strides that the glottis was nearly occluded. One may say that any case of hoarseness or aphonia which does not yield to ordinary measures in a month requires careful laryngeal examination. A cord invaded by a carcinomatous ulcer or growth is not necessarily immobile. If the cord is fixed and immobile we know that the growth is very deep; if it is mobile the growth is early, and operation holds out a prospect of cure. We are on the threshold of further developments in the treatment of this form of cancer. Rose and Harmer have shown many successful cases of intralaryngeal carcinoma treated solely by radium, and I know one patient with extrinsic carcinoma of the larynx who, three or four years ago, seemed doomed to die, but after radium treatment remained alive and well until quite recently.

A patient who consulted me some years ago illustrates a form of chronic hoarseness which may be called parasyphilitic.

He gave a definite history of syphilitic infection, for which he had been treated. His glottis was distorted, and portions of the cords had been destroyed, hypertrophied nodules from the one appearing more or less to fit into the gaps from the other. There was general pharyngeal congestion and hypertrophy of the superior ventricular bands; movements were good. No treatment seemed to be availing, and on account of his occupation the patient could not keep silent. As I regarded the condition as precancerous I took the opinion of a clinical meeting, at which I was advised by some to leave the case alone, and by others to be prepared to operate. I favoured the former view, and have left the case alone. As far as I know the man is still in vigorous health, but I am convinced that he should be kept under observation, as malignant changes are likely to take place.

Another patient with the same symptoms presented himself the other day. There was complete fixation and swelling of the right side of the larynx, though without definite ulceration. The patient's condition was good; there were no enlarged lymphatic glands in the neck, and the Wassermann reaction was positive. The condition is one of syphilitic perichondritis of the thyroid, and the patient is now undergoing anti-syphilitic treatment. At the same time he will be carefully watched, as the combination of malignancy with syphilis is not uncommon.

Laryngeal Paralysis.

Finally, one may consider cases in which laryngeal paralysis results in aphonia or hoarseness. Bilateral paralysis is uncommon, and generally is the result of some severe nervous affection, such as bulbar palsy. Paralysis of one cord, due to intrathoracic growth, aneurysm, or pressure on the recurrent laryngeal nerve from thyroid and oesophageal growths, is often accompanied by no more than weakness of voice. If laryngeal sensation is present the lesion is probably below the larynx. On the other hand, if anaesthesia is present, the possibility of an intracranial lesion or pressure on the vagus nerve must be considered. When a patient suffers from aphonia or weak voice after operation on the thyroid the possibility of trauma must not be overlooked.

ESTIMATION OF HEPATIC EFFICIENCY.

REPORT ON THE EXPERIMENTAL INVESTIGATION OF A NEW TEST BASED ON THE USE OF SODIUM SALICYLATE.

BY

WILLIAM RALSTON, M.R.C.S., L.R.C.P.,
B.Sc.LOND., F.I.C.,
ASSISTANT IN THE HALE CLINICAL LABORATORY, LONDON HOSPITAL.

ROCH AND SCHIFF (Geneva) in 1921 suggested a new test of hepatic function based on the use of sodium salicylate, and H. Thiers in 1927[1] described a modification of their method. A brief account of this test appeared in the *British Medical Journal*,[2] and the present paper records some experiences with the test, the work having been undertaken on the suggestion of Dr. J. R. Marrack, chemical pathologist of the Hale Clinical Laboratory, as such a simple test—if universally accepted as reliable—would be of great value in diagnosis.

Nature of the Test.

H. Thiers "states that a normal adult can assimilate a dose of 0.04 gram (=3/5 grain) of sodium salicylate, no trace of salicylic acid being found subsequently in the urine. If the liver is damaged salicylic acid appears in the urine passed during the second to the seventh hour after the ingestion of the sodium salicylate." In the preliminary experiments described below the method used by Thiers—namely, extraction of the urine in a flask, and then testing the extract for salicylic acid with dilute ferric chloride—was closely followed, and positive results were obtained with a normal adult. During the later experiments the method of extraction was improved (as shown by the tabulated results) by using a glass-stoppered separating funnel, and it was proved that as much salicylic acid was excreted by normal adults as by those with diseased livers.

Preliminary Experiments.

After preparing the three solutions required for the test, a patient with a diseased liver (Case A, Table II) was selected for the first trial, and as the results obtained seemed to confirm the claim made for it, the next test was done with a healthy adult (Case 1, Table I). The same

results were obtained as with Case A, and thus were contrary to the statement on which the test is said to be based. It was therefore considered advisable to repeat the test on the same healthy adult. Salicylic acid was again found present in the second specimen of urine and, this time, in the first specimen also (Case 1a, Table I). The result with the second specimen in Case 1 was thus confirmed, and the negative result with the first specimen could be explained as possibly due to inexperience with the method, and to the apparatus used for extraction being to some extent unsuitable.

These results raised a very grave doubt as to the reliability of the statement that normal adults could assimilate sodium salicylate and no trace of salicylic acid would appear in the urine, especially as a reference to the pharmacology of salicylic acid showed that "it appears in the urine very soon after its ingestion [ten to thirty minutes], but the elimination goes on slowly."[3]

Later Work.

These trials were done to remove this doubt, and the test was carried out with three other healthy adults and three more patients with diseased livers. Details with results have been tabulated below, followed by notes on the laboratory work. The cases referred to in Table I were four healthy adults who had never had any illness suggestive of liver disease, and they were therefore chosen as normal adults, all being males, their ages ranging from 16 to 55 years. Table II refers to four cases treated in

the hospital, having diseased livers as shown in the "Diagnosis" column of the table. The first specimen of urine was collected one hour after the dose of salicylate was given, and the second specimen four hours later.

Notes on the Laboratory Work.

1. The chief aim was to detect any trace of salicylic acid present in the urine, and not merely follow a procedure which might give a negative result although a trace was in fact present. A comparison between the results of Cases 3 and 3a illustrates how a negative result may occur as a consequence of some incomplete extraction, as, when the second specimen of urine in Case 3 was re-extracted, twenty times more salicylic acid was proved present than was found by the first extraction. The only negative results obtained occurred with the two cases first tried, and one of these at least was proved as probably incorrect by the second trial giving positive results (Case 1a), as already explained.

2. The first specimen of urine in every case ranged from 22 c.cm. to 78 c.cm., and so the entire specimen in each case was used for the extractions.

3. The second specimens ranged from 71 c.cm. to 216 c.cm., and as these were not too inconvenient to extract the entire specimen was again used, except in Case C, where it was halved for the purpose explained below.

4. In the earlier extractions the ether was shaken up with the urine in the 8-oz. wide-mouthed stoppered bottle used for collection, and the separation of the emulsion was performed by transferring successive portions of the mixture to a glass-stoppered burette; but the bottle stoppers did not fit very well, the process was somewhat messy, and the separation was tedious. So after the experience with Case 3—where the salicylic acid (proved present in both specimens) was so much less than in the previous cases—a conical glass-stoppered separating funnel was obtained and used for the re-extraction in Case 3a, and for all the later extractions.

5. In cases B, C, and D bile pigment was present in the urine, and was extracted by the ether along with the salicylic acid. In case B the ethereal layer was not completely evaporated before adding to the ferric chloride, and on mixing the liquids the aqueous layer showed a distinct purple tinge while most of the bile pigment remained in the ethereal layer. In Cases C, 3a, 4, and D the ethereal extract was evaporated to a small bulk, and the bile pigment combined with the violet colour due to the salicylic acid, the resultant colour being a brown.

6. To test whether extraction by rotating vigorously in a beaker with ether could be complete, the urine of Case C was thus treated, and then, after separation of the ether (by use of the separating funnel), the urine was re-extracted by shaking with a fresh lot of ether in the funnel. The extraction of the first

specimen of urine in the beaker proved to be complete, the re-extraction giving no salicylic acid. The second urine specimen was halved, and one half (108 c.cm.) was extracted twice as above, the other half being used as a check by extracting once only by vigorously shaking in the separating funnel. In this instance the beaker method gave no colour indicative of the presence of salicylic acid, whereas the second extraction gave a distinct trace (*a*, Case C). The check half of the urine gave a more distinct trace (*b*, Case C). These results, therefore, indicate that the open beaker method is the less reliable of the two.

7. In Case D the extract gave a more decided colour reaction than any of the others with bile pigment present, and it was interesting to find that the effect of the yellow bile pigment could be exactly imitated in the tubes with the violet standards by mixing with a few drops of the yellow solution of potassium chromate.

Summary.

The foregoing is a report on work done in trying a new test for hepatic efficiency, based on the use of sodium salicylate, as described in the *British Medical Journal*.

The preliminary work consisted in trying the test on a selected patient, and then comparing the result with that obtained with a normal adult. As the results were the same in both cases further investigation was considered necessary, especially as a doubt arose about the reliability of the statement that "normal adults could assimilate a 3/5-grain dose of sodium salicylate, no trace appearing later in the urine."

The later experiments were carried out with three more normal adults and other three cases with damaged livers, all the results being shown in tabular form, followed by a discussion of the tables in the form of notes, explaining how and why the method of extracting the salicylic acid was slightly varied, and pointing out that bile pigment modified the violet colour of the salicylic acid test to a brown, which could be matched in the standard colour tubes by the addition of potassium chromate.

Conclusion.

1. The tables show that salicylic acid appeared in the urine of each of the four healthy adults after the ingestion of a small dose of sodium salicylate, as well as in that of four other cases with damaged livers.

2. Its appearance in the urine of the first hour confirms the statement quoted in reference to the pharmacology of salicylic acid, and does not support Thiers's statement.

3. The tables show that no distinction can be made by means of this test between the four normal adults and the four cases with damaged livers.

From the above results it is concluded that this test, as described in the publication referred to, can be of no use in classifying cases with damaged livers, or in measuring the extent of the damage.

BRONZED DIABETES IN A WOMAN.

BY

G. M. W. HODGES, M.B., B.S.

I VENTURE to publish these notes on account of the rarity of bronzed diabetes in women, and because this case seems to have run an unusual course. The patient was seen at the maximum of bronzing by three other medical practitioners, who could suggest no other diagnosis; one who had previously seen a case (in a man) thought the bronzing typical.

The clinical details available are as follows.

Family History.—The grandparents all lived to advanced ages; the father died of uraemic coma at the age of 74, and the mother died of the same complaint at the age of 70. There were eight children, of whom the patient was the eldest. She was perhaps mentally the brightest of a not very bright family. The next in age, a male, died of "cancer of the liver," aged 50; he was congenitally blind. The third, also a male, died of epilepsy at the age of 30. The fourth, a female, is living, mentally deficient and congenitally blind. The fifth, a male, is living and is normal. The sixth, also a male, is alive and normal, but mentally he is rather dull. The seventh, a female, is living; she is mentally deficient and congenitally blind. The eighth, a male, is living, and is normal. None of them show any signs of syphilis, and two who have been examined (the fourth and seventh) give negative Wassermann reactions.

Personal History.—This gives nothing of importance. The patient was a very stout woman, but exceedingly active. Her chief ailments have been flatulent dyspepsia and some cardiac insufficiency. She had had no medical attention for five years.

Clinical Details.

On November 11th, 1927, the patient was deeply jaundiced, with anorexia, but no sickness and no diarrhoea. She had become much thinner since the previous May, the loss of flesh coinciding with extreme thirst.

The liver was easily felt two inches below the costal margin, and the spleen about the same. Both were smooth, regular, and soft. The liver was slightly tender. Nothing else abnormal was found. The heart sounds were normal, but muffled, and the lungs were normal. The urine contained much bile pigment, but no albumin; sugar was present in large quantity. At this time there were on the forehead and forearms what appeared to be a few freckles.

The jaundice cleared up under treatment in ten days. The patient was put on a strict non-carbohydrate diet. The urine sugar rapidly diminished, and early in December, 1927, the urine contained only a trace. A blood examination gave 65 per cent. haemoglobin and a normal white cell count.

On December 12th there was a sudden rise in the urinary sugar, and acetone was present. The patient became partially comatose, and had apparently marked pain over the spleen. She remained in this condition, sometimes rousing and sometimes completely unconscious, for a month, the heart gradually getting weaker and dropsy developing; but the sugar had completely disappeared from the urine on December 20th, and was never found again until just before her death.

During this period pigmentation became very apparent, involving the face, neck, forearms, and both groins, with scattered patches on the abdomen, back, and both thighs. The pigmented spots were of all sizes up to a threepenny piece, many coalescing. Her face presented a curious appearance—a mottling of yellow shading up to deep bronze on a skin almost mauve in colour. There was incontinence of urine and faeces, and bedsores developed. By this time the liver and spleen both reached halfway from the costal margins to the umbilicus.

From the middle of January, 1928, she began to improve. The heart regained its tone; her colour became normal except for the bronzing; the bedsores healed; the appetite returned. In July she was downstairs, walking in the garden, and doing needlework. The bronzing was beginning to fade. From now on she was seen and the urine examined at fourteen-day intervals.

On November 9th, 1928, five days after the last visit, she suddenly complained of feeling very ill—"just as I did before." The urine was found to contain a fair amount of sugar. She became comatose on November 10th, and died the following day.

Post-mortem Findings.

Only a partial necropsy was allowed. There appeared to be no pigmentation of the peritoneum. There was little free fluid, and this was clear. No abnormal mass or tumour could be found. The liver was about two and a half times its normal size, and appeared uniformly enlarged. It was smooth, rather soft, and pale; it was densely adherent posteriorly. The gall-bladder and duct were normal. The spleen measured roughly 9 in. by 5 in.; it was smooth, extremely friable, and adherent to the periphery and omentum. Both kidneys were enlarged and soft. The heart was enlarged and infiltrated with fat; the valves showed no disease. There was some staining of the pericardium, but not enough to be definitely called pigmentation.

Pathologist's Report

Portion of Spleen.—There is general slight chronic perisplenitis. The pulp is soft. A few dark points are seen. The Malpighian bodies are not easily distinguished and not much fibrosis can be discerned.

Liver.—There is generalized monolobular cirrhosis with much yellow pigmentation along the prolongation of Glisson's capsule. The liver substance is fatty.

Pancreas.—The glandular tissue is largely replaced by fat. No pigmentation can be distinguished.

Suprarenals.—Soft, but normal.

Kidney.—It is slightly enlarged and soft. The cortex is not clearly diminished; it is pigmented and yellow. The capsule strips leaving a number of arterio-sclerotic depressed patches of various sizes. The pyramids show whitish streaks towards the papillae.

Microscopic Examination.

Spleen.—The pulp is of a loose fibrotic texture; the Malpighian bodies are atrophied. The trabeculae appear normal, but hyaline emboli are present in some of the vessels. There are no gross lesions anywhere to be seen. Many of the cells contain pigment granules, and free granules are also present, but it is not possible to say how much of this is due to *post-mortem* change. The fibrous reaction of the spleen is feeble and consists of occasional blue granules.

Liver.—There is a moderate increase of fibrous tissue along Glisson's capsule. In the liver cells bordering the portal spaces there is a great increase of pigment. Marked cellular exudation is evident in Glisson's capsule. The bile ducts are normal and not increased in number. The cellular inflammatory infiltration consists of a proportion of polymorphs, more marked in the periphery of Glisson's capsule. There is a small amount of haemosiderin in the liver. It is mainly confined to the neighbourhood of the intralobular veins. There is no excess of haemosiderin in the portal spaces.

Pancreas.—There is shrinkage and atrophy of some of the acini, and in others the nuclei are stained more deeply than normal; some catarrh of the duct is present. The islets of Langerhans are present.

Kidney.—There is generalized chronic interstitial nephritis. In many parts of the section the descending loops of Henle are necrotic, probably due to *post-mortem* changes. There is some arterio-sclerosis and degeneration of some of the glomeruli up to complete atrophy. Here and there round-celled infiltration can be seen. There is much catarrh of the collecting tubules, and some of them contain cells full of pigment. The epithelium of the collecting tubules is impregnated with grains of pigment.

It is regrettable that the patient and her family absolutely refused her admission to hospital, where a more thorough clinical examination would have been possible.

My thanks are due to Dr. A. G. Gibson of Oxford for his kind interest in the case, his advice, and his examination and report on the *post-mortem* specimens.

LOCAL ANAESTHESIA IN OPERATIONS FOR HAEMORRHOIDS AND FISSURE OF THE ANUS.

BY

T. HENRY TREVES BARBER, M.D., B.Sc.,

LONDON.

THE use of a local anaesthetic for the operative treatment of haemorrhoids and fissure of the anus has many advantages over a general narcosis.

1. Any one of the numerous operations advocated for the cure of haemorrhoids can be performed quite painlessly, including the most painful procedure—the most dangerous of all with a general anaesthetic—dilatation of the sphincter ani.
2. Its innocuity, both local and general.
3. Its local action, lasting several hours after the operation, thereby curtailing the duration of after-pains.
4. The ease with which it can be employed.

These are all compensations for the extra time required in making the necessary number of injections and the following of an exact technique such as that to be described.

The use of dilute solutions for local anaesthesia (as here used) was first introduced by Schleich, but to Reclus belongs the merit of their popularization and their use in rectal surgery, more especially in operating on piles. For all practical purposes the method here given is his, with, however, some modifications which have been found to be useful. The solution for these operations which is recommended is composed as follows:

Novocain	0.5 cg.
Adrenaline (1 in 1,000)	24 minims
Physiological saline solution	100 c.cm.

Mix and sterilize.

It will be noted that the amount of adrenaline is small, but in practice it will be found to be ample (a dilution of 1 *in* 1,000,000 will produce a local ischaemia) for rendering the field bloodless, without fear of any subsequent sloughing, notwithstanding the large amount of the solution employed. It is, however, important that the percentage should not be stronger than indicated, and the injections must be well spaced so that a considerable extent of the subcutaneous tissue is infiltrated. When injection is not confined to a localized zone of tissue sloughing never occurs.

The injections are made in the following manner. The patient, having been duly prepared in the usual way, is put in the lithotomy position, the legs resting on some appropriate supports. (1) About six small pledgets of cotton-wool are first prepared, their diameter being that of the little finger and their length one inch. They are tied in the middle with a piece of silk or linen thread, one end of which is left four or five inches long to be used as a tractor for removal. Pour into a sterilized receptacle 15 to 20 c.cm. of the solution, and place the pledgets in it. With the aid of a pair of artery forceps introduce the saturated pledgets one by one into the anus, asking the patient to "bear down" meanwhile; this renders the mucous membrane insensitive and relaxes the sphincter ani, as shown by the gaping of the anal orifice. (2) Swab with iodine the anus and surrounding skin. (3) Take an all-glass 5 c.cm. syringe and fill it with the solution; adjust an ordinary (not too fine) hypodermic platinum or nickel needle, push it into the cellular tissue at the junction of the skin and mucous membrane, and begin the injection. Push the needle along slowly, distending the tissues ahead of the needle-point with the solution; in this manner the fluid is infiltrated without pain. The first needle prick is all the patient need ever feel during the whole course of the operation. When the syringe is empty, withdraw the needle, refill and insert it again just beyond the middle of the swelling made by the previous injection. Repeat these injections *in the same way so as to encircle the anus*, special care being taken to go slowly when crossing the middle line, for the sensibility on the opposite side has not been affected by the injections already given. In all from six to eight injections are necessary—equal to 30 to 40 c.cm. of the solution. (4) Now remove the pledgets by traction on their threads; they will almost fall out by themselves. Fill the syringe and use a long medium-sized platinum or nickel needle. (5) Insert the forefinger of the left hand into the rectum, hook the internal sphincter with it so as to steady it and draw it down. (6) Pierce the tissues perpendicularly to the previous injections and at the same level: push the needle well into the sphincter, injecting meanwhile. It is of the utmost importance to steady the muscle so that it shall not slip away from the needle; this may be quite difficult to do towards the end of the injections, as the sphincter will be felt to "fade away," it having lost tonicity almost completely. Encircle it with six or seven injections—equal to 30 to 35 c.cm. of the solution. The insensibility will now be complete.

Wash the hands again (it is always well to wait about five minutes after the last injection before beginning the operation) and proceed with the preliminary requirement to all rectal operations—namely, stretching of the sphincter ani. In cases of simple fissure this may be all that is necessary to effect a cure; in others, and in fistulae, excision, curetting, and the use of the actual cautery can all be employed painlessly, the patient only experiencing a sensation of touch and the realization that something is being done. If piles are present they are now dealt with by any of the numerous methods, according to the choice of the operator. I prefer Mitchell's technique in general to all other methods for the removal of piles, whether pedunculated or with intervals or sulci; with a pair of Kocher's artery forceps clamp the pile and cut off the upper part. A running suture of catgut is passed under and over the forceps, a tie having been made after the first stitch under the clamp at the distal end of the pile to control more securely its blood supply. Now withdraw the clamp; pull the suture taut and tie it off. This is a very safe method, as the sutures will not slip, thus assuring complete haemostasis. The raw edges are turned in, and are therefore less painful. Any number can be dealt with; the results are excellent. A short piece of large rubber tubing, wrapped round several times with a strip of gauze well smeared with a 1 per cent. antipyrine ointment, is inserted. It relieves pain, and at the same time acts as a compressor against haemorrhage; it permits the free passage of flatus while controlling spasm, and can be removed in twenty-four hours or sooner should it cause discomfort.

I have used this method of local analgesia since 1910, and have never seen a complication of any kind nor a single slough induced by it in the considerable number of operations in which it has been used. The only likely complication is retention of urine, which is encountered also in general anaesthesia; this is due to the way the sphincter has been dilated.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CARDIOSPASM TREATED SUCCESSFULLY BY OPERATION.

I THINK it desirable to record the following details of a case of cardiospasm which was treated with remarkable success by the operation of Mikulicz.

A man, aged 25, had for six years suffered from progressively increasing difficulty in swallowing. He stated that the food appeared to be arrested in the lower part of the chest, and could only be made to pass by drinking water with each mouthful, whereupon the food passed with a jerk. Epigastric pain was frequent, coming on usually three or four hours after food; this was often succeeded by vomiting, which at once relieved the pain.

On examination the patient was found to be thin, but otherwise in good condition. A radiographic examination revealed the typical appearances of cardiospasm, with enormous oesophageal dilatation and a well-defined constriction at the lower end.

After preliminary passage of an oesophageal rubber tube I opened the abdomen by a right paramedian incision above the umbilicus. The anterior wall of the stomach was incised longitudinally, midway between the greater and lesser curvatures, and the whole of the right hand was introduced into the interior of the stomach; the index finger was then inserted into the lower end of the oesophagus. Considerable resistance was at first presented to the passage of the finger, but this was overcome by steady pressure, and the middle finger was inserted alongside the index. Separation of these two fingers resulted in sufficient dilatation of the obstruction to permit the introduction successively of the ring and little fingers. The incision in the stomach was sutured by two layers of catgut, and the abdomen was closed. The patient made an uninterrupted recovery from the operation, and at the end of two weeks was able to swallow normal food without difficulty. There has been no recurrence of any symptoms.

An *x*-ray photograph taken three months after the operation showed that the oesophageal dilatation had almost entirely disappeared, and that there were no signs of the constriction revealed in the pre-operative skiagram.

A. C. MACONIE, M.B., B.S.Lond., F.R.C.S.Eng.
Shanghai.

SPLENIC ENLARGEMENT AND RAW SPLEEN.

THE following case of atypical leukaemia, and its extremely rapid improvement under treatment, may be of interest.

Mrs. X, aged 48, first came under my notice during the early days of July, 1928. She complained of progressive swelling of the body since the previous February, palpitation and breathlessness on the slightest exertion, and complete inability to tackle any of her usual household duties. I also elicited the information that she had lost several pounds in weight, and that for the previous two years she had had several "floodings" (metrostaxis). On examination I found an extremely enlarged spleen fully occupying the left half of the abdomen, reaching to the pubes below and extending well beyond the middle line. The notches were distinctly felt. No enlarged lymph glands were found anywhere. Fully confident that this was a myelogenous variety, on July 3rd I took a blood smear, a differential count of which gave the following surprising result: Polymorphonuclears 2.25 per cent., small lymphocytes 97 per cent., large hyalines 0.50 per cent., transitionals 0.25 per cent. Nothing abnormal was seen in stained red cells. There was apparently a marked leucocytosis.

On the advice of a consultant the patient was admitted to the Leeds General Infirmary, a provisional diagnosis of atypical lymphatic leukaemia having been made. Here she was placed on the usual benzol and *x*-ray treatment for fourteen days. Two blood counts were taken, one on July 5th and the other on July 10th. That taken on July 5th was as follows: Red cells 3,570,000, leucocytes 35,000, haemoglobin 52 per cent., colour index 0.73. The red cells appeared normal, the lymphocytes were of small type, but much larger than normal. A differential count showed: Polymorph neutrophils 3 per cent., lymphocytes 97 per cent. The result of the blood count taken on July 10th was as follows: Red cells 4,170,000, leucocytes 14,700, haemoglobin 50 per cent., colour index 0.60. The film showed irregular size and staining of red cells with some polychromatophilia. A differential leucocyte count showed: Neutrophil polymorphs 8.5 per cent., lymphocytes 91.5 per cent.

The patient was discharged from the Infirmary on July 19th, with the spleen only slightly decreased in size. She returned on two separate occasions, fourteen and twenty-eight days later, for *x*-ray exposure. After her return home I placed her on large doses of iron, strychnine, and arsenic, and advised her to take regularly raw spleen. Since July 19th she has taken on an average twelve to fourteen raw sheep's spleens per week. Marked improvement in her general condition began to show itself. She has now gained 16 lb. in weight, there is no palpitation, no breathlessness, no lassitude, and no metrostaxis. She feels very fit and can manage all her usual household duties (this she has been able to do since September). Her spleen, though still enlarged, is greatly reduced in size, and on December 7th a further blood count was taken. This showed: Red blood cells 4,850,000, leucocytes 3,870, haemoglobin 68 per cent., colour index 0.7. Differential count: Polymorphs 46 per cent., lymphocytes 46 per cent. (small 42.5 per cent., large 3.5 per cent.), large hyalines 5.5 per cent., cosinophils 2 per cent., basophils 0.5 per cent. Nothing abnormal was found in stained films.

I am given to understand that the improvement in this case is much greater than is usual with *x*-ray and benzol treatment, and it would be interesting to know whether other splenic conditions, notably myelogenous leukaemia, would react in the same way. The accompanying diagrams illustrate the spleen at various stages of the illness.

I am deeply indebted to Mr. D. Chamberlain, honorary surgeon at the Leeds General Infirmary, for permission to use his clinical data, and to Dr. S. Goodman Platts, of the York County Hospital, for his excellent blood counts.

Reports of Societies.

ACUTE INTESTINAL OBSTRUCTION.

AT the meeting of the *Medical Society of London* on February 25th, Dr. J. WALTER CARR *presiding*, a discussion on the subject of "Acute intestinal obstruction" was opened by Professor A. H. BURGESS of Manchester, President-Elect of the British Medical Association.

Professor Burgess began by saying that the present century had witnessed a great improvement in the surgical treatment of acute abdominal crises (he protested strongly against the inelegant term, which was of London coinage, "the acute abdomen"). So far as Manchester Royal Infirmary was concerned, the mortality from acute appendicitis in 1924 was one-twelfth of what it had been in 1900; the mortality from perforations one-seventh, and the mortality from acute intestinal obstruction one-half. He referred to the statistical compilation of cases of acute intestinal obstruction brought forward by Mr. H. S. Souttar in the Section of Surgery at the Annual Meeting of the British Medical Association in 1925, which was the largest and most authoritative series of statistics available. It covered the period 1920–24, and the returns from seven hospitals, three in London, three in the provinces (including Manchester), and one in Ireland. He hoped that Mr. Souttar would compile a further series for the following five-year period and present it to the Winnipeg Meeting of the Association in 1930. Professor Burgess adopted Mr. Souttar's figures, but modified them by cutting out all cases of strangulated hernia and acute intussusception, for the simple reason that there was no excuse for missing the diagnosis in either of these conditions, and he wanted the statistics to represent those cases of acute intestinal obstruction the diagnosis of which was not readily obvious. This left 1,042 cases, in which there had been 395 deaths, a mortality of 37.9 per cent. It was this mortality which must be reduced. In Manchester some reduction had been effected. Thus the mortality for the ten-year period 1913–22 was 41.07 per cent., for 1920–24 (the period covered by Mr. Souttar's tables) 33.5 per cent., and for 1925–27 only 30.2 per cent. What was the reason for this continuing high mortality? The main reason was delay in the application of surgical treatment. The early signs of acute intestinal obstruction were not sufficiently stressed in the textbooks, at least in those of rather older date. Far too much emphasis, for example, was usually placed upon faecal vomiting. This should never be regarded as a sign of acute intestinal obstruction; it was really an end-result. There was a tendency to wait for the

development of faecal vomiting before diagnosing obstruction; in other words, to wait for a complete and perfect clinical picture. But there was only one hand that ever painted a complete and perfect clinical picture of a pathological condition, and that was the hand of death. The man who waited for faecal vomiting would never make a mistake in diagnosis, but rarely would he save his patient. Acute intestinal obstruction, Professor Burgess continued, might be either primary or secondary. It might come as a "bolt from the blue," or be simply a process engrafted upon a long-standing chronic condition. In distinguishing between a primary and a secondary obstruction there were two clinical features which were important. In secondary obstruction which had been grafted on to a chronic condition one frequently saw the outlines of individual dilated coils and visible peristalsis passing along. Sudden acute obstruction always led to dilatation, with thinning of the wall, but never to visible peristalsis. Whenever the outline of dilated coils was seen, with the peristaltic wave passing along, one might be absolutely certain that it was a case of obstruction which had been in existence for at least several weeks. Sometimes, even when peristalsis was not visible, it was palpable. By keeping the hand over the abdomen the coil underneath could be felt alternately hardening and softening. That condition of palpable peristalsis, again, indicated obstruction of some considerable standing. Primary acute intestinal obstruction varied in acuteness of onset. In general terms, the higher the obstruction—that is, the nearer the stomach—the more acute the symptoms. The early symptoms of acute primary intestinal obstruction were common to those of any other acute abdominal crisis; they were the symptoms which, years ago, were described by Sir Frederick Treves as "peritonism." They were of reflex origin, and had no localizing value whatever. In the case of acute intestinal obstruction, the pain was always referred to the epigastric region. The pain was often paroxysmal at first, becoming continuous as the obstruction became complete. The vomiting, like the pain, was at first of a reflex character; later on it was due to mechanical obstruction. The higher the site of obstruction the earlier the vomiting. It was most marked in the highest type of obstruction, the condition known as acute dilatation of the stomach. When the obstruction was low down, as in growths of the rectum or lower sigmoid, vomiting might be absent. The vomiting was at first gastric, later bilious, and presently assumed a faecal character; its persistence, however, was its most important feature. Distension of the coil above the site of obstruction must, of course, be present, but it was not always visible. If the case was seen early the distension might be localized and furnish a guide to the site. Vomiting and distension varied inversely to each other. In high obstruction, vomiting was marked, and distension not marked; in low obstruction the converse obtained. Distension was the most unfavourable feature; it made the operation much more difficult, and markedly increased the shock. The speaker pleaded for auscultation, which was of great value in diagnosis. Certain sounds, after a little experience, were quite unmistakable. By auscultation one could distinguish between the turbulence of the mechanical obstruction and the death-like silence of the paralytic. Rectal examination was of value also, especially in discovering the ballooning of the rectum which was so frequently made out when there was growth in the sigmoid region. In Mr. Souttar's list, out of 1,019 cases where the site of obstruction was stated, 586 were in the small intestine, and 433 in the large. At Manchester the experience was different; there more cases of obstruction were found in the large intestine than in the small. In one analysis of 280 cases, 90 were in the small, and 190 in the large. The keynote of the position was the condition of the caecum. If the obstruction was in the colon the caecum must be distended; if in the small intestine, it must be collapsed. If obstruction were located definitely to the large intestine the cause was likely to be a malignant growth; 91 per cent. of obstructions in the large intestine (leaving out strangulated hernia and intussusception) were due to this cause. If the obstruction were definitely made out in the small intestine the chances were 300 to 1 against the condition being a malignant growth. As to treatment, this, in definite mechanical obstruction, could only be operation. There were accessory treatments, of which the most valuable was gastric lavage. The nature of the operation would depend on the stage of the disease. In the early case, with little distension, and good general condition, an ordinary exploratory laparotomy might be done to discover where the obstruction was, and either remove it, short circuit it, or make an artificial anus, in that order of preference. In late cases, the less done, provided it was effective, the better. If the obstruction was located definitely to the colon he thought one should content oneself for the time being with a "blind" caecostomy, which would, at any rate, relieve the obstruction. It was true that one was still left ignorant as to the exact site and cause, but this information could be obtained later; with a patient in the throes of acute obstruction all that mattered was to relieve the obstruction by the shortest and least shock-producing method. If, however, one was not sure that the obstruction was in the colon, an exploratory laparotomy must be done. While a "blind" caecostomy was recommended for obstruction in the large intestine, a "blind" enterostomy was by no means to be done in the small, because of the extreme likelihood of leaving behind a strangulated coil, which would inevitably lead to the death of the patient.

Dr. C. H. S. FRANKAU emphasized the necessity of differentiating between the obstruction due to a growth, gradual in onset, and the acute obstruction due to such an occurrence as strangulation by a band. Toxaemia was always present within a few hours of the onset of acute intestinal obstruction, owing, he thought, to the rapid multiplication of anaerobic bacilli in the bowel. His personal opinion was strongly averse from "blind" caecostomy; he had only done one such operation in eighteen years. He had never regretted doing a preliminary exploration, the advantages of which were that one could ascertain the site of the obstruction for the subsequent operation, or could remedy the obstruction there and then if possible. The disadvantage was a certain prolongation of the operation, but this should not be for more than ten or twelve minutes at the most. He performed the old-fashioned muscle-splitting incision, preferring to expose the caecum fairly freely. He disapproved of the method of sewing in a soft rubber tube; it was safer to bring a portion of the caecum out through the abdominal wall, to which it could be securely attached. In the type of obstruction due to strangulation, if any bad distension were present the prognosis was grim. Acute obstruction was apt to be mistaken for food colic, especially if the patient's story of what he had eaten at a recent meal were unduly regarded. The giving of castor oil without result helped to rule out food colic. The speaker added a few words about ileus, where there was no mechanical obstruction. He thought this might be divided into three categories: (1) ileus following injury, which was troublesome, and might be persistent, but was rarely, if ever, fatal; (2) post-operative ileus, where there was no antecedent peritonitis, and none subsequent to operation; here bile given by the rectum might afford relief; (3) ileus as a sequel to peritoneal inflammation, where the main standby was fluid given freely and continuously by the rectum and by the mouth also if circumstances allowed.

Mr. H. W. CARSON said that the higher the obstruction the more definite the symptoms, and the lower the obstruction the more definite the signs. In excluding hernia and intussusception Professor Burgess had done right, but unfortunately he cut off those cases in which the greatest advance had been made, and in which the death rate was much lower than in former years. Why did people die from intestinal obstruction? If a case were followed out to its final stages it would be found that the patient suffered from an extraordinary condition of toxaemia, dying quite suddenly, almost unexpectedly, from what seemed to him poisoning of the heart muscle. He thought there was a good deal to be said for the theory that it was gas gangrene toxaemia, and he himself had had some extraordinary results from the use of anti-gas gangrene serum.

Mr. ZACHARY COPE commended anti-gas gangrene serum, which during the last three years had made a great

difference in his own practice. He described some cases almost moribund which recovered. Undoubtedly in a certain proportion of cases anti-gas gangrene serum was a specific. He was himself an advocate neither of "blind" caecostomy nor of extensive exploration; the procedure must be adapted to the individual case, and to an estimation of what the patient would stand, in which latter respect the determination of systolic and diastolic blood pressure was very useful.

In further discussion, Mr. T. H. BENIANS complained of the loose use of the term "toxaemia" by surgeons. These toxins were practically all of one type; the important thing was the route that they followed. Mr. HOPE CARLTON, in connexion with what had been said about auscultation of the abdomen, mentioned a sign which he had learned abroad, that in primary peritonitis, either pneumococcal or streptococcal, a great increase in the conduction of vocal sounds from the chest through the abdomen was heard over the symphysis pubis. Dr. A. E. ROCHE, in selected cases of post-operative ileus, had seen dramatic results from pituitrin, given intravenously. Mr. DICKSON WRIGHT mentioned the importance of taking steps to overcome the alkalosis.

Professor BURGESS, in reply, said that there was no real antagonism between the view that some of the symptoms were due to anaerobic bacilli and that some were due to absence of bile. Both factors might be at work. The danger of treating with bile, however, as the exponent of the method, Mr. Brockman of Sheffield, had himself shown, was that though the symptoms cleared up the patient might die. The mechanical obstruction remained, and the disappearance of symptoms was apt to be deceptive. With regard to "blind" caecostomy the speaker advocated this at the Annual Meeting of the British Medical Association in 1923, and he had seen no reason to change his views. After the patient had been "tided over" in this manner, one could, at leisure, obtain the necessary information.

PREVENTION OF DENTAL DISEASES IN CHILDREN.

AT the meeting of the Section of Odontology of the Royal Society of Medicine on February 25th, Mr. GEORGE NORTHCROFT presiding, a "casual communication" from Dr. J. KINGSTON BARTON was read on "The prevention of diseases of the teeth in children."

Dr. Kingston Barton stated that when he started in general practice, just fifty years ago, having plenty of spare time, he attended the out-patient departments of several of the children's hospitals in London, and also was fortunate enough gradually to develop a fairly large practice amongst young mothers and children. Impressed by the importance of the teeth, he printed, for free distribution amongst his patients who were mothers, sheets containing particulars of the milk dentition, the order of cutting, and the age at which (between the seventh and the twenty-fourth month) the different teeth were usually cut; then he asked that, in blank spaces provided, the age at which the teeth actually came through should be inserted, and he pointed out that any great delay in cutting should be reported to the medical adviser. The sheet also contained a diagram to enable the mother to distinguish the different teeth, as well as a number of warnings and instructions with a view to preventing the onset of rickets, which was almost invariably the cause of delayed teething, and to ensure that the infant had food of the right kind. A specimen sheet was thrown on the screen. For twenty-five years, said Dr. Barton, he kept careful records of all the mouths which came under his observation. He found that a good state of the teeth and jaws was always associated with breast-feeding; the next best was seen in infants fed on ass's milk, or goat's milk, or fresh cow's milk; and the really bad teeth were found in children who had been hand-fed on various kinds of tinned or preserved milk foods, some of which were much worse than others in their ill effects. He also laid great stress in his practice, a generation ago, on the misuse of starch foods as given to infants. During the past twenty years it had been the fashion to scoff at the views expressed about the ill effects of starch, but in Professor Mellanby's most recent paper he noticed that emphasis was laid upon the ill effects of too early use of various cereals in infant feeding. In the sheet just mentioned Dr. Barton had written: "Too early use of sago, rice, and bread, particularly if not well cooked, will also set up rickets." He had added, "As the germs of the permanent teeth are being formed in the gums whilst the milk teeth are cutting, any disorder of nutrition which affects the one set will also affect the other. Hence delayed teething of the milk set is often the precursor of delicate and decayed permanent teeth; this, again, being one common cause of delicate manhood and womanhood." Dr. Barton said that there was really only one way of preventing early disease of the teeth in children, and that was by the insistence on proper breast-feeding, or, if this was absolutely impossible, on the use of pure fresh cow's milk. He also deprecated the sweets and sticky foodstuffs with which modern children were plied at all times of the day, to the utter corruption of their teeth.

The PRESIDENT of the Section said that he thought it would be the general wish that the dentition diagram shown by Dr. Kingston Barton should be handed to the curator of the odontological museum at the Royal College of Surgeons. It was extremely interesting evidence of what was done by one general practitioner in the early eighties in anticipation of modern odontological science.

THE SIGNIFICANCE OF CHOLESTEROL.

AT a meeting of the Liverpool Medical Institution on January 17th Dr. E. NOBLE CHAMBERLAIN read a paper on the significance of cholesterol in physiology and pathology.

Dr. Chamberlain gave a brief account of the physiology concerned, mentioning as possible channels of excretion the bile, intestinal mucosa, and the skin. He said that the last of these seemed to have been neglected in the literature, but since cholesterol was contained in appreciable amounts in the superficial layers of the skin, desquamation of these would lead to its loss. To make up for this the body probably absorbed cholesterol from the food, but at certain times it required a supplementary supply which was produced by synthesis, the most likely site for which was in the suprarenal glands. This view had been put forward by the French school some years ago, and, though denied by the German school, it had received support from personal observations by Dr. Chamberlain. Further, the vital nature of the suprarenal glands seemed to be intimately related with the abundance of cholesterol present in their cortex. The uses of cholesterol were summarized. It was required for the constant repair of cellular tissues, during the breakdown of which some was undoubtedly lost. The cholesterol was supplied through the medium of the blood, in which it was contained in approximately equal amounts in both corpuscles and plasma. It occurred in a free form and as esters. Esters were principally contained in the plasma. In any individual, the blood cholesterol was constant in amount. This was due to a proper balance between intake and excretion and between synthesis and destruction. It was suggested, on experimental grounds, that a finer mechanism for regulation of blood cholesterol might reside in the spleen. In the growth of the central nervous system an adequate supply of cholesterol was essential, since this system was very rich in cholesterol. Cholesterol had notable antihaemolytic properties, particularly against substances of the saponin group. It played some part in processes of blood coagulation and sedimentation of the red cells. The development of immunity was closely associated with a rise of blood cholesterol, and it had been thought that cholesterol might have an important part in the production of immunity. In fat metabolism, again, cholesterol was constantly associated with the other fatty bodies, and it seemed likely that it took a prominent part in the metabolism of fats. Lastly, the discovery that irradiation of ergosterol led to the formation of the important vitamin D had once more

drawn attention to its close chemical relative, cholesterol, for although ergosterol was probably supplied from plant food in ordinary circumstances, it was possible that cholesterol itself might form an additional source in the body. The relations of cholesterol to certain important pathological problems were next considered. In nephritis, especially of the chronic parenchymatous variety, marked rises in blood cholesterol were common, and the degree of hypercholesterinaemia was usually proportionate to the degree of oedema. In cases where the oedema disappeared but the hypercholesterinaemia remained, the prognosis was generally unfavourable. Acute nephritis showed somewhat similar changes to the chronic parenchymatous form, but chronic interstitial nephritis was not accompanied by hypercholesterinaemia, unless the dominant feature of the case was arterio-sclerosis. Arterio-sclerosis alone was usually associated with a rise of blood cholesterol, and the connexion between the two, though unexplained, was interesting in view of the experimental production of atheroma in rabbits by cholesterol feeding. Unfortunately, however, these experiments had not so far been reproduced in carnivorous animals. The hypercholesterinaemia of diabetes was next considered. A suggestion as to its causation was made, and stress was laid on the fact that it formed a reliable and easily estimated measure of the degree of lipaemia, which was usually, itself, an index of progress in severe cases of diabetes. In diseases of the liver, jaundice of an obstructive nature was usually accompanied by increase of blood cholesterol, due to retention of cholesterol usually excreted through the medium of the bile, while haemolytic forms of jaundice, on the contrary, were generally associated with low blood cholesterol values. The estimation of blood cholesterol might therefore be of value in distinguishing between the two types of jaundice. A brief review of the relation of cholesterol to gall-stones followed. After dealing with current theories, it was suggested that should the liver be shown experimentally to be capable of converting cholesterol into bile salts, a failure of this function might result in increased concentration and deposition of cholesterol in the bile. There seemed little doubt that the formation of stone was due to some disturbance of cholesterol metabolism, but the nature of this disturbance was as yet unknown. Reference was then made to the low blood cholesterol values found in most forms of anaemia, and the effect of splenectomy in cases of acholuric jaundice and splenic anaemia in producing a return of cholesterol to normal values. The common presence of anaemia in malignant disease rendered low values common in this disease, though high values were often recorded in the absence of anaemia. In cancer, also, it had been found that the plasma cholesterol was greater than that for whole blood, the reverse of the state of affairs in normal people or in other diseases.

In bacterial infections of any severity, also, hypocholesterinaemia was generally present, and was usually proportionate to the intensity of the infection. This observation had been extended in cases of prostatic obstruction to determine those cases—namely, with a low blood cholesterol content—which were liable to extension of urinary sepsis. This work needed confirmation. Lastly, brief mention was made of the deposition of cholesterol in various tissues, such as the arterial walls, xanthomatosis, and in the retina or vitreous.

OPERATIONS ON THE GALL-BLADDER.

A MEETING of the Section of Surgery of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on February 8th, with Sir WILLIAM DE COURCY WHEELER (in the absence of the president) in the chair.

Mr R. A. STONEY read notes on a case of choledochoduodenostomy, and gave the following clinical details.

A woman, aged 50, was admitted to hospital with a second severe attack of jaundice in the course of four months. She had an irregular temperature, but no rigors; there was at first marked tenderness of the right hypochondrium and epigastrium, which gradually lessened, revealing a hard mass in the middle line, the gall-bladder not being palpable. At the operation the gall-bladder was slightly distended, but no stones were felt in the bladder or ducts. There was a large dark blue swelling in the right border of the gastro-hepatic omentum. The gall-bladder was separated from the liver, and the cystic duct was traced into this swelling. Bile was aspirated. A free incision was made into the swelling, and bile mixed with pus was evacuated in large quantity. A finger was passed down into what felt like the os uteri in the region of the head of the pancreas, which was enlarged and very hard; no enlarged glands were palpable. Anastomosis was secured by a double row of circular sutures between the opening in the common duct and the adjacent second stages of the duodenum. The gall-bladder and cystic duct were cut away, and a drainage tube was introduced through the stumps of the cystic duct into the common hepatic duct. A small tube and strip of gauze were passed down to the line of anastomosis, and the wound was closed round the tubes. There was free drainage of bile for the first twenty-four hours only. The small tube and gauze were removed on the third day, and the tube in the hepatic duct was left out on the tenth day. The wound rapidly healed without leakages; jaundice disappeared, enlargement of the pancreas diminished, and the patient left hospital on the twenty-fourth day after operation.

Attention was drawn by Mr. Stoney to the necessity of determining whether an anastomosis would be necessary before separating the gall-bladder or seriously injuring it, since in most circumstances an anastomosis between the gall-bladder and intestine was easier than between the duct and the intestine. In cases of infection the latter operation might be more suitable, because it allowed direct drainage of the ducts on the surface as well as providing a short circuit.

Sir WILLIAM WHEELER said that in his own experience the operation of anastomosis between the gall-bladder and the stomach was, as a rule, comparatively simple; he had been struck with the fact that there was no post-operative vomiting, and that the convalescence of the patients was unhampered by any unpleasant symptoms. Difficulties arose when there had been previous operations, especially if a biliary fistula was still present. In patients who had been operated upon several times the difficulties in connexion with the surgery of the common bile duct were notorious. He had found, on one occasion, after opening the duodenum, that the introduction of an instrument in retrograde fashion had been a great help in recognizing the duct and in locating the site of a traumatic stricture. He had on three occasions performed end-to-end suture of the common duct without any post-operative trouble. In one case, a doctor who had been operated on several times for biliary obstruction without success, the duodenum was opened, and a small cyst of the common bile duct was found in the region of the ampulla of Vater. By incising the cyst the obstruction was relieved and the patient remained well.

Mr. ARTHUR CHANCE said that he recently had two cases exactly similar to those of Mr. Stoney. There was a hard mass in the head of the pancreas; the common bile duct was dilated to the size of a 10 c.cm. syringe, and had a vivid bluish-green colour. In one case he had performed cholecysto-gastrostomy, and in the other cholecystenterostomy. It was not always easy to obtain a bloodless area in the right half of the transverse mesocolon through which to bring the small intestine, and Mr. Chance thought that cholecysto-gastrostomy was, owing to its easier performance and better after-results, probably the best routine procedure.

Mr. W. DOOLIN referred to three cases in which he had employed cholecystenterostomy, and said that there had been no sign of jaundice when the patients left hospital on the thirty-seventh day after operation. In cases in which cholecystectomy had been performed previously, and in which strictures of the common bile duct were encountered, operation was very difficult. It was, he thought, almost impossible to make a differential diagnosis between cases of chronic pancreatitis and carcinoma of the pancreas.

Mr. A. A. MCCONNELL mentioned a case of congenital cystic dilatation of the common bile duct on which he had operated twelve years previously, draining the cyst satisfactorily. At the time the patient had complained of no symptoms except abdominal swelling, and the cyst had been found to contain pure bile. If he had then been more familiar with the operation of choledocho-duodenostomy, he would have performed it. In some cases which he had operated on since, he had made a primary anastomosis between the cyst of the common duct and the duodenum, and the patients had got well.

Mr. F. J. HENRY mentioned a case of a woman, aged 40, who had been ill for about six weeks with vague abdominal discomfort and jaundice. At the operation the gall-bladder was found to be moderately enlarged and the ducts moderately dilated, but no stones were visible. The duodenal wall was opened and the ampulla excised, the condition being diagnosed microscopically as a primary carcinoma of the ampulla of Vater. The patient was now perfectly well, and, in view of this, Mr. Henry was inclined to doubt whether the case was one of malignancy.

Mr. STONEY, in replying, said that in cases in which he had brought about an anastomosis between the gall-bladder and the stomach he had been impressed by the absence of vomiting after the operation, and by the easy convalescence. The relief afforded by the operation in his cases had been very considerable. He thought that a differential diagnosis between chronic pancreatitis and carcinoma of the pancreas was often impossible even after an operation had been performed. When adhesions were found after a prolonged fistula, the difficulties were so great as to be almost insuperable. He believed that the only thing to do was to try to find the dilated head of the duct, and make an anastomosis between it and the duodenum. It was surprising what good results could be obtained in these cases.

Rectal Narcosis with Tribromethylalcohol.

Mr. F. J. MORRIN read a paper on rectal narcosis with avertin (tribromethylalcohol). He said he had used this in 54 cases—too few, perhaps, for any general deductions. The oldest patient was 69 and the youngest 3 years old. Excluding four cases in children where the anaesthetic was unsatisfactory owing to non-retention of the enema, anaesthesia failed in only one case, an alcoholic subject. It was light in eight cases, but did not hinder the completion of the operation; the results were good from the operative standpoint in the remainder of the cases, though of course of varying depth. Two patients had a marked fall of blood pressure, long post-operative sleep, and a weak and rapid pulse, which was not restored to normal for four days; the symptoms were obviously due to overdosage. Thirty-six of the patients were cases of advanced carcinoma of the tongue and face; they were suffering from cachexia and were extremely bad anaesthetic subjects, being unsuitable for any other form of anaesthesia. The condition was the so-called "inoperable carcinoma" and was treated by diathermic coagulation with a very powerful diathermy apparatus; it necessitated very deep anaesthesia, and the danger of ignition contraindicated ether. Avertin, in addition to securing effective anaesthesia by allowing accessibility to the growth and free intraoral manipulation, rendered the surgical treatment of these conditions very satisfactory. Mr. Morrin said he had been most favourably impressed with the efficacy of the new drug, which he considered the anaesthetic of choice in toxic goitre. A brief experience with avertin amylene hydrate led him to regard it as a more effective anaesthetic agent, giving better abdominal relaxation, more certain anaesthesia; it was not associated with shallow respiration, and was less liable to be attended with a fall of blood pressure. No post-operative bronchitis or pneumonia was observed, despite the fact that many of these aged patients were operated upon for disease of the mouth and pharynx. Mr. Morrin said that care was necessary in preparing the solution accurately, and the dose of 0.1 gram per kilo of body weight was only rarely exceeded. When it was necessary to increase the dose cautious fractional administration was advised. Where the body weight was decreased by the operative removal of a large amount of tissue in a subject of poor vitality, overdosage with avertin might possibly occur, as, for example, in the case of amputation of a limb.

Sir WILLIAM WHEELER thought that Mr. Morrin's enthusiasm for the drug was justifiable. The patient apparently passed into a somnolent state within ten minutes; this contrasted sharply with anaesthesia with oil ether, the great difficulty about which was the varying time it took to act. An operation under this anaesthetic could not be timed within three-quarters of an hour, since some patients went under much quicker than others. There was apparently no antidote for avertin, and there was a greater fall in blood pressure than when oil ether was used. The better administration of avertin was, he thought, a matter of experience. He was interested to note the absence of post-operative symptoms following its use, since after oil ether the patients were sometimes very sick and some developed bronchitis.

Dr. J. BECKETT said that there seemed to him to be a great deal of complicated technique in the giving of avertin. This was not the case with the oil ether method, which was very simple.

Mr. W. DOOLIN congratulated Mr. Morrin on being the first surgeon outside Germany to have had an opportunity of testing the new drug. The intention of the German authorities that avertin should not be available for general use until it had been given an exhaustive trial in competent hands was praiseworthy. Opinions in Germany as to its employment were very divided; it was used either as a basal narcotic, preceded by other narcotic substances, and with additional ether administration, or else as the sole narcotic medium, and it was in the latter group that most accidents had occurred. To judge from published reports the difficulties of administration were rather more serious than Mr. Morrin had stated; it had been repeatedly said that even slight errors of technique might lead to serious effects in patients. The chief dangers were overdosage and overheating. The rapid fall of blood pressure had led to fatal secondary haemorrhages in a few cases, and fatal necrosis of the colon had been reported as the result of overheating the drug before injection. Many observers working with the drug had admitted that the chief disadvantage was the fact that it was impossible to "steer" the anaesthesia so produced. Some had considered that the dosage by body weight was unsatisfactory; it was impossible to state at any time how much of the drug injected had been absorbed into circulation. Its advantages were enormous when the anaesthesia was successfully performed. The abolition of vomiting during and after the operation was beneficial to the patient, particularly so in the case of children. Reports in German literature during the past two years showed a marked falling off of post-operative pulmonary complications. There seemed little doubt that, notwithstanding these dangers, avertin was a great step forward in the technique of anaesthesia.

Dr. P. MACCARVILL, who had assisted Mr. Morrin when he started using avertin, said that a 3 per cent. solution had been used, but it had been found difficult to get the powder to dissolve, and later they had used a 2.8 per cent. solution, which was sufficient to be retained by the rectum. The fluid was heated first to 45°C. and cooled to 40°C. The thirty-six cases in which he had assisted Mr. Morrin had all been malignant, mostly carcinoma of the tongue, and these were very difficult cases for anaesthetics. He personally thought that ether was out of the question in such cases, and gas was reported to be bad. On the first occasion he had given avertin he had felt rather alarmed, as the patient's blood pressure had fallen considerably, and the breathing had become extremely shallow, but the operation had been quite successful. When administered with care he regarded avertin as an invaluable anaesthetic.

Mr. A. A. MCCONNELL referred to the possibility of using diathermy in the mouth when rectal ether was being employed; he had been doing so for many years, and had not, at any time, experienced any difficulty.

Mr. MORRIN, in replying, said that he had obtained the avertin from a clinic in Berlin. He had tried rectal oil ether extensively, and thought that there was no comparison between the two anaesthetics. There were many dangers from oil ether also. There was no great technical difficulty in preparing avertin. The mortality following its use had occurred in the early stages, when too big doses had been given, and when it had been used in hepatic disease and in renal cases, which were quite unsuited to it. He had only had one case in which it had not been possible to complete the operation; that was an alcoholic case, and it was not realized then that such patients were not suited to the drug. In cases where the blood pressure fell very low, he had found that ephedrine controlled the fall. He had never seen a case of secondary haemorrhage occur.

Reviews.

DEFORMITIES.

In his foreword to Dr. M. F. FORRESTER-BROWN'S handbook on the *Diagnosis and Treatment of Deformities in Infancy and Early Childhood*,[1] Sir ROBERT JONES very properly insists on the value of the work and commends it to a large audience. Dr. Forrester-Brown has had a remarkably wide experience of orthopaedic practice in the United States, and in many European countries, where she has used a travelling scholarship to the fullest advantage. In her own preface she defines the book as "a supplement to the larger textbooks of orthopaedics, or more properly as a sort of scout to prepare the way for them." Every orthopaedic surgeon knows how many hospital beds are filled with cases which, properly attended to in their early stages, would never have had to come into hospital at all, or, being there, would have required far less severe or prolonged treatment. Dr. Forrester-Brown's book aims at the education of medical practitioners in the recognition of deforming diseases in their early stages, and in the practical application of the old saw "a stitch in time saves nine."

The subject-matter is arranged on a regional basis, under five headings. The first of these is the neck, back, and thorax, in which subject Dr. Forrester-Brown is thoroughly at home. As a disciple of Goldthwait of Boston, she has done at Bath much good work on postural errors, and has had most gratifying results, some of which are illustrated in this section, in the restoration of muscle tone and the consequent correction of errors of attitude. The remaining four sections deal briefly but clearly with the shoulder and elbow, the forearm and hand, the hip-joint and knees, and the feet. While there is no attempt to describe all the known affections of a part, there are succinct accounts of most of the conditions likely to be encountered, for fuller details the reader being referred to the large works on orthopaedic surgery. In the last forty-three pages the author sets forth the principles of treating deformities of the legs and feet. Here we think she does not give enough credit to the curative action of steel instruments, when these are intelligently designed and properly fitted. The brilliant results of operations, and the increased and more intelligent application of plaster-of-Paris, have led to some neglect of the work of earlier orthopaedic surgeons in the use of "walking instruments," but we must do Dr. Forrester-Brown the justice of noting that she states that in many cases knock-knee of considerable severity can be corrected with calliper splints.

This book is a short one, the descriptions and directions are clear, and the illustrations instructive. The busy practitioner should therefore be able to find the time to read it and to refer to it whenever he is confronted with a case of suspected or obvious deformity. Widespread use of such a work should in time diminish the crowd of cases which have to be treated in hospitals by specialists at the expense of the charitable public and the overburdened ratepayer or taxpayer.

LABORATORY WORK ON TUBERCULOSIS.

THE introduction to Dr. H. S. WILLIS'S book, *Laboratory Diagnosis and Experimental Methods in Tuberculosis*,[2] has been written by ALLEN K. KRAUSE. After such an accolade, the value of which will be appreciated by tuberculosis workers all over the world, the reviewer's task may seem redundant. This book of 330 pages consists of five parts; in the first we find a description, mainly from the clinical aspect, of the secretions, excretions, and constituents of the body in so far as they relate to the diagnosis and treatment of tuberculosis. The second part deals with the various methods of detecting the tubercle bacillus, and with its isolation and cultivation; it is therefore mainly a description of laboratory technique. The third part is devoted to diagnosis by tuberculin, and again the subject is considered mainly from the clinical aspect. Serological diagnosis occupies the short third part; there is a chapter by Dr. J. S. WOOLLEY on complement fixation, and another on the remaining serological tests and their value. This section might, with advantage, be considerably elaborated. Finally, a description is given of the technique of the various methods of studying artificially produced tuberculosis in animals. The material is good, but Dr. Willis's book is either too big or too little. He mentions in his preface that it is intended for "practising physicians, public health officials and laboratory workers in general, and medical students." The practising physician would welcome more information on the clinical application and value of the tests mentioned, and be content with less about the laboratory technique; the laboratory worker would probably prefer the balance shifted in the opposite direction; the medical student would like the whole subject-matter condensed and set out more dogmatically. The person who will most appreciate the book as it stands is the isolated sanatorium physician who has to do his own laboratory work; but even he, realizing the author's wide knowledge of the clinical pathology of tuberculosis, will regret its condensation. In these days of specialization it is unusual to find a book that contains a mixture of clinical and laboratory teaching, without going very deeply into either; its welcome will depend on the personal opinion and wants of its readers. The author's style is clear and pleasant, the illustrations are good, and the type is legible, but printer's errors are rather frequent.

Dr. ANDRÉ BRETON has contributed a very useful addition to the literature of tuberculosis by placing on record a careful clinical study of Vernes's flocculation reaction of serum in the presence of a resorcin solution.[3] In Dr. Breton's hands this test has proved valuable in the diagnosis and prognosis of all forms of tuberculosis, and especially of the pulmonary type. Like other laboratory tests, such as that based on the red cell sedimentation rate, its value in diagnosis is restricted, and is mainly negative, since nearly all acute and many chronic infections give positive reactions. The chief claim made by the author for this reaction is that it provides an accurate index of the activity of the tuberculous infections in 90 per cent. of the cases examined; this is as near accuracy as any serum test can go. Dr. Breton is enthusiastic about the method, but level-headed and fair in the conclusions he draws. His zeal has tempted him to put up a dummy in the shape of the complement fixation reaction, with which he has compared the Vernes reaction in every case, but the complement fixation reaction is not generally considered of any particular value in tuberculosis, either for diagnosis or as an index of activity. Dr. Breton's work on the Vernes reaction is good enough to stand on its own merits, and gains nothing by the comparison. The performance of the test might have been dealt with in greater detail, and especially the technique of the photometric method of reading the results. In describing the method he gives a useful warning that the blood serum must be taken from a patient who has fasted for twenty-four hours and who has had no drugs for seventy-two hours, and that it must be examined before it is twenty-four hours old if the results are to be of any value. Does the Vernes reaction merely confirm the clinical estimation of a case, or does it give premonitory warning of increase or decrease of activity of infection? The author tells us he does not yet feel justified in answering his questions. This is a valuable, well-printed monograph containing a full bibliography of the subject.

EPILEPSY.

DR. W. G. LENNOX and DR. STANLEY COBB are to be congratulated on having published as a monograph their review of *Epilepsy*,[4] which recently appeared in *Medicine*. They indicate in a subtitle that the scope of their work is confined to "the standpoint of physiology and treatment," and they rightly recognize that a knowledge of the physiology of convulsions is fundamental to the study and treatment of epilepsy. It is the difficulty of the physiological problems involved which renders progress so slow in this field of neurological research. The authors wisely begin by defining epilepsy as a syndrome rather than as a disease, leaving open the question of the relative importance of general and focal factors in its etiology. A valuable discussion of the possible neurological mechanisms of convulsions follows. A large part of the book is devoted to a consideration of the evidence for and against the existence of abnormalities outside the central nervous system in epileptics. The various systems of the body are serially reviewed, and the large number of recent investigations into the metabolism of epileptics are judicially discussed. Special consideration is given to disturbances of acid-base equilibrium and the reduction of the seizures by induced acidosis. Dr. Lennox and Dr. Cobb conclude that, in spite of the frequent occurrence of organic cerebral abnormalities of various kinds in patients suffering from epilepsy, such lesions are contributory causes only. A knowledge of the functional abnormalities of nervous tissue is essential for further progress. The evidence indicates that in certain epileptics subject to frequent seizures these may be precipitated by oxygen lack and by alkalosis, and prevented by increased oxygen tension in the tissues and by acidosis. Yet these physiological changes are also to be regarded as merely contributory factors. "The important question yet remains, why, under a given stimulus, one person should have a seizure and another not." Hence we are led to postulate some unknown constitutional element. This "convulsive capacity" is presumed to be present in each person with epilepsy, and hence there is justification for the conception of "essential epilepsy" as a name for that underlying explosive tendency to which cerebral lesions and metabolic abnormalities act only as triggers. This constitutional element remains for the present a mystery. This conclusion, derived from the labours represented by some six hundred references, may seem somewhat disheartening. Nevertheless, we may find encouragement in the tendency of recent research to concentrate on factors influencing the reactivity of the nerve cell, for it is in this direction that we must surely look for further light upon the convulsive predisposition.

X-RAY DIAGNOSIS OF ECHINOCOCCUS CYSTS.

As a supplement to *Acta Radiologica* DR. GUNNLAUGUR CLAESSEN publishes in book form a monograph entitled *The Roentgen Diagnosis of Echinococcus Tumors*.[5] The author, as a justification for this work, observes that although there are a good many papers on the subject to be found in various journals they are all very scattered, and his endeavour has been to collect in one place the sundry experiences related by other authors in this branch of radiology, and to add to the subject his own experiences of forty-four cases which he has himself examined with x rays. While the radiological aspect of the subject is the most prominent, other points are by no means overlooked, and chapters are included which deal with the biology and morphology of the echinococcus, with the geography of the disease, with the pathological changes apt to occur in the cysts, etc. The book deals mainly with the disease as it affects the liver, and there are few references to cysts in other parts of the body. The methods of x-ray examination are explained, and the various radiological appearances examined from the points of view of their reasons and their diagnostic value. In summarizing, the author states that out of his forty-four cases, thirty-seven were cysts of the liver, and that twenty-eight were verified by operation; that pathological changes in the cysts due to either senility or to infection are common, and that these affect the x-ray picture. The illustrations consist of four figures in the text and eighty-two radiographs and photographs bunched together at the end. This method of putting all the illustrations together at the end with no descriptions other than those in the text is irritating; if illustrations are to be inserted in this manner there should be a short description attached to each, and not merely a reference number. We may say that these illustrations are very good. There are, in addition, short summaries in German and French, and references to one hundred and thirty-seven papers. The English translation is by Robert Fraser. The whole forms a very complete account, radiologically and otherwise, of a comparatively rare disease, and should be of use to those interested in the subject.

ANNALS OF MEDICAL HISTORY.

WITH the fourth instalment of last year the first series of the *Annals of Medical History*,[6] started in America in 1917, comes to an end. But fortunately for lovers of medical history this beautifully got-up journal, edited with so much devotion by Dr. FRANCIS PACKARD, is to be continued in a second series with a different format (7½ x 11 instead of 8¾ x 12½) but without any reduction in the reading matter, for there will be six instead of four numbers in the year. Although most successful from a literary standpoint the *Annals* do not pay their way. It is to be hoped that the increasing number of medical men who take an interest in the history of their profession will come to the rescue. The present number is so full of attractive matter that space does not allow of even a complete enumeration of the contents. Three articles deal with last year's tercentenary of the publication of the *De Motu Cordis*; the editor gives a running account of the Harvey celebration in London last May; Professor J. J. R. Macleod, now of Aberdeen, publishes his well-illustrated address on Harvey's experiments on the circulation; and the frontispiece of Michael Servetus has a bearing on Sir Humphry Rolleston's admirable Mary Scott Newbold Lecture on the predecessors and contemporaries of Harvey, which appears as the opening paper. The portrait of Benjamin Rush on the cover is accompanied by Dr. W. S. Middleton's account of the doings of this great physician during the yellow fever epidemic of 1793 in Philadelphia. From a study of the notes taken in 1818 at the lectures on the practice of physic, of Nathaniel Chapman, professor of medicine from 1816 to 1850 in Philadelphia, Dr. D. L. Farley sketches the activities of the founder of what afterwards became the *American Journal of the Medical Sciences*. The editorship of a rare anthology entitled *A Full View of all the Diseases Incident to Children* (erroneously ascribed to John Martyn in the eighteenth century) is discussed by Dr. Ernest Caulfield, who also sketches the writers quoted in the volume. Dr. LeRoy Crummer now publishes the manuscript of William Heberden's "Introduction to the Study of Physic," which, like the "Prefatory Essay," brought out in the last number of the *Annals*, is now for the first time printed. In his historical survey of diabetes, which is carried up to the present day, Dr. J. H. Barrach rightly points out that more has been learnt about this disease during the last forty years than in the previous eighteen centuries. In philosophical vein Dr. Stephen D'Irsay discourses on the evolution of the physician's attitude, and rather curiously the article immediately preceding it is Dr. W. E. Aitchison Robertson's well-told story of the famous Mary Tost, who pretended to be the mother of many rabbits. Under the title of "The Evolution of our Table" Dr. Cecil Striker treats of ancient habits of diet. An extremely interesting article, "The Sponge, its Effect on the Martyrdom of James King of William" (the remarkable nature of this reformer's name being duly explained), describes the hurtful

state of San Francisco in the fifties, which King, who "dared to say what others feared to think," strove to correct, and, indeed, by his death accomplished. Dr. Jonathan Wright, an ever-faithful contributor, writes on "The Foundations of Science and Religion in Dante's Debt to Aristotle," Dr. Alfred Brown on John Arderne, and Dr. J. L. Bragman on the "Medical Wisdom of De Quincey."

THE COMMON COLD.

IT is at a very appropriate time that Dr. LEONARD HILL, who has done so much in the way of applying physiological guidance to the maintenance of health, and Mr. MARK CLEMENT have brought out a book on *Common Colds: Causes and Preventive Measures*,[1] so clearly written that the layman can read and benefit from the inward digestion of its contents. After some introductory remarks on the anatomy and physiology bearing on the subject and a chapter on the psychological aspect of catching cold, there follows a discussion of the causes of colds; the factors favouring infection are fully set forth, and, as elsewhere in the volume, the importance of fresh air as a means of avoiding infection is brought out. The most infectious stage of a cold is the earliest, before the second or wet stage has come on. An incidental reference is made to non-contagious colds, not due to infection from other cases, but caused by irritating agents and vapours, of which tobacco has been incriminated as one of the commonest. Vasomotor catarrh and coryza due to hypersensitiveness are briefly touched upon, and in speaking of influenza the suggestion is thrown out that the great plague of Athens in 429 B.C. may have been of this nature. The treatment of this too familiar ill by salicin, as advocated by Mr. E. B. Turner, and by methyl arsenate of sodium (arrhénal), said by Romary to be a specific, is summarized. As already mentioned, much stress is laid on the prevention of colds by fresh air, diet, light, and proper clothing. The discordant opinions as to the value of vaccine therapy are also quoted. With regard to curative treatment it is pointed out that the original dictum "If you are fool enough to stuff a cold, you will produce and have to starve a fever" has in its abbreviated form come to imply almost the exact opposite as regards the treatment of a common cold. The various methods of attempting to cure a cold are noticed, and approval is expressed of the old-fashioned plan of a Dover's powder and hot lemonade to increase sweating, and Epsom salts next morning. Support is not given to much whisky as a remedy.

NOTES ON BOOKS.

MRS. CALLOW'S *Food and Health*[2] is a volume that sets out, in a straightforward and sensible manner, some of the important facts about diet that should be understood and appreciated by the public. There is every reason why persons of average intelligence should learn the simpler facts upon which the science of dietetics is based, to the benefit of both their comfort and their pocket. On the economic side the general reader's attention might be drawn to the section that deals with patent foods.

Dr. J. K. WATSON'S *Handbook for Nurses*[3] is the weightiest book for its size with which we are acquainted. This makes it tiring to read, but is accounted for by the author's attempt to give in one volume all the information that nurses can possibly require. To this end a new chapter on mental disease has been added to the present edition, the eighth, of the book, together with one hundred new illustrations. The issue to date of 95,000 impressions of the work attests the publishers' claim that it is a standard textbook; but if further editions are called for a distribution of weight between two volumes might aid the nurse's comfort. Another book on the same subject, Miss MARGARET S. RIDDELL'S *Lectures to Nurses*,[4] has reached its third edition. To this book also much new matter has been added, including sections on surgical tuberculosis, on the nursing of special operations, and on new growths. A useful additional feature is a glossary of technical terms. This will doubtless be increased and improved in future editions. At present there seems no reason why a nurse should be told the meaning of the popular term "quinsy," and left to imagine what the equally non-technical word "carbuncle" denotes. The introduction, while advocating tactful treatment of doctors, instils proper awe in the presence of a matron.

The comparative anatomy and development of the nervous system is always a most fascinating subject to those who have the knowledge to appreciate it, and it is to those few that ARIËNS KAPPERS'S *Three Lectures on Neurobiotaxis and other Subjects*[11] will appeal. There are three lectures, the first dealing with neurobiotaxis, the second with the phylogenetic and ontogenetic development of the corpus striatum, and the third with the development of the cerebral cortex and the functions of its different layers. These three lectures were delivered at the Universities of Copenhagen, Lund, and Upsala in 1927, and are reprinted from the *Acta Psychiatrica et Neurologica*.

The forty-eighth volume of the *Transactions of the Ophthalmological Society of the United Kingdom*[12] embodies the full text of the various communications read before the society during the session ended April, 1928, together with the reports of the transactions in 1927-28 of the affiliated societies, which include the Midland, North of England, Irish, and South-Western Ophthalmological Societies, and the Scottish Ophthalmic Club, and of the proceedings of the Oxford Ophthalmological Congress, 1928. The volume, which is well printed and illustrated with numerous photographs, line drawings, and coloured plates, is in every way a credit to British ophthalmology.

In publishing *Typical Flies*,[13] of which the third series is now before us, Mr. E. K. PEARCE'S purpose is to present photographs of British diptera so as to assist the student, especially when he is commencing to study these insects. Some of the photographs are helpful, because they give a general impression of the appearance of the insect, but many of them are indifferent; even the venation is out of focus in some, though that is one of the few "characters" which should be easily reproduced in a photograph. Many small points of importance in the systematics of the diptera cannot be adequately shown in a photograph. The short notes beneath the figures add little to the value of the book; there must be a thousand British insects which might be described as "a black fly, pupa dark brown."

INFANT FEEDING: A CORRECTION.

IN our review of Dr. Howard Gladstone's *Clinical Observations on Infant Feeding and Nutrition* (February 23rd, p. 357), we stated in error that the author, in giving the calorie values of diets, had failed to indicate whether these values refer to an ounce, a feed, or a day. In a cross-heading, on page 34, he makes it clear that the reference in each case is to one pint.

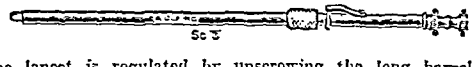
PREPARATIONS AND APPLIANCES.

LANCET FOR PERITONSILLAR ABSCESS.

MR. A. A. MILLER, assistant out-patient registrar, Central London Throat, Nose and Ear Hospital, writes that the instrument illustrated—a modification of the well-known blood-letting lancet—has been devised to meet the difficulties so often experienced in opening a peritonsillar abscess; he has found it very reliable. The length



of the lancet is regulated by unscrewing the long barrel into which it is fitted. By pulling the handle the lancet is made to disappear in the barrel, and at the same time a spring is compressed by a special device which keeps the lancet under tension in the desired position; the tension itself can be regulated. On pressing the handle the action of the spring is released and the lancet let loose with considerable force, thus producing a sharp and instantaneous cut. The manipulation of the instrument is very simple. It is made by Messrs. Charles King of Devonshire Street, W.

INTRACRANIAL SURGERY.

A STUDY of Intracranial Surgery, based upon the work of Dr. Harvey Cushing's clinic at the Peter Bent Brigham Hospital, Boston, has been prepared for the Special Report Series[1] of the Medical Research Council by Mr. Hugh Cairns, who was assistant resident surgeon to the clinic during the period 1926–27. Dr. Cushing's clinic is devoted solely to the study of neurological surgery, all its members being trained both in the details of neurological examination, including perimetry and ophthalmoscopy, and in the performance of intracranial operations. During the period under review 463 cases were admitted to the clinic, of which 359 were classified in the "intracranial tumour group." On 284 members of this group major intracranial operations were performed, with the remarkably low operative mortality of 9.8 per cent. The operative mortality in intracranial surgery is, in Dr. Cushing's view, largely what the surgeon wishes to make it; he may achieve a low mortality by the exercise of due caution, a high mortality by attempting radical operations on tumours difficult of access.

Pathology of Tumours.

From a table showing the pathology and situation of all the verified brain tumours which came to operation or necropsy, it is evident that the commonest tumour was the glioma, which was found with equal frequency in the cerebrum and the cerebellum. In the cerebrum the commonest sites were the frontal, temporal, and parietal lobes. Next in order of frequency was the meningioma, whose site of election was the parietal lobe and the juxta-ampullary region. Adenomata and adeno-carcinomata, also occurring in the juxta-ampullary region, are almost as frequent as meningiomata. It is worthy of note that though in discussing the histology of brain tumours, especially of gliomata, the work of Cushing and Bailey is referred to at length, no mention is made of the excellent work of Greenfield in this country.

The Need for Immediate Treatment.

Mr. Cairns, in considering the treatment of intracranial tumours, reaches the conclusion that all brain tumours must be regarded as emergencies, no matter how mild their symptoms may be when they first come under observation. The onset of grave symptoms may be extremely sudden, and it is impossible to predict at what period in the course of a case such symptoms will supervene. Early treatment is required, moreover, in view of the papilloedema and optic atrophy. Loss of vision is apt to be insidious and scarcely noticed until the final stages, when it may occur with astonishing rapidity, even in the course of a few days only. Dr. Cushing maintains that the surgeon must shoulder the responsibility of acting on his own diagnosis, a view which is in accordance with the teachings of Horsley, Macewen, and Sargent in this country.

Methods of Clinical Examination.

It is estimated in the report that fully 40 per cent. of intracranial tumours, chiefly of the pituitary and acoustic nerve, give rise to definite clinical syndromes. The need for thorough systematic examination of each case is made evident by the fact that approximately 4 per cent. of all brain tumours are metastatic, the common sites for the primary focus being the breast, lungs, kidneys, and skin.

The administration of hypertonic salt solution, either intravenously or rectally, is advocated very strongly in those cases which are admitted in a state of coma, on the ground that it causes the brain to shrink in size and thus reduces intracranial tension. In cases suffering from minor degrees of drowsiness it is sufficient to administer magnesium sulphate, by mouth if possible, or, if the patient is liable to vomit or is unable to swallow, by rectum. Within six to twelve hours the patient will have become brighter and more co-operative, though in view of his liability to ture quickly great care will be needed to shepherd him through a complete neurological examination. No harm has ever resulted from the use of this method.

[1] Special Report Series, No. 125. Medical Research Council. His Majesty's Stationery Office. 1929. 3s. net

The Prevention of Blindness.

In every patient admitted a complete examination of the fundus oculi is undertaken. This examination is of paramount importance, as in many cases of intracranial tumour the chief aim of treatment is to preserve vision. In cases of slow-growing tumours, so situated that they may cause pressure effects on the optic nerves or chiasma without producing hydrocephalus, there may be for years few or no symptoms save progressive failure of vision. Of the cases under review 44 were admitted almost totally blind, vision being reduced to 20/100 or less in both eyes, and 27 were blind or almost blind in one eye. Neglect of ophthalmoscopy may result in failure to detect the presence of a tumour until vision is gravely damaged. Investigation of the visual fields is almost as important as the examination of the fundi. In Dr. Cushing's clinic the workers depend almost entirely on perimetry to differentiate between cerebellar tumours and those not infrequent temporal and occipital tumours which give cerebellar signs.

Radiography.

Another very important aid to diagnosis of intracranial tumour is the x-ray examination. The tumours most likely to give positive x-ray findings are adenomata of the pituitary and intracranial meningiomata, the former giving rise to enlargement of the sella turcica, the latter in many cases to erosion and increased vascularity of the bone, or to diffuse thickening and enlargement of the meningeal vessels. Ten per cent. of the gliomata in the clinic showed calcareous deposits. During the year under review 35 per cent. of intracranial tumours were revealed by means of x rays. Ventriculography, or x-ray examination of the ventricular system after the injection of air, was employed in 37 cases, the method being reserved for those cases in which all other means had failed to reveal the situation or presence of a tumour.

Treatment.

Underlying Cushing's surgical procedure are three main principles: (1) to avoid injury to the brain; (2) haemostasis; and (3) asepsis and closure of the wound. Very long operations, far longer than any of the operations of general surgery, are rendered possible by the application of these principles. The average length of an intracranial operation in Cushing's clinic is about three hours, while some operations last as long as six or seven hours. Whenever possible local anaesthesia is used, and the greater part of the operating is done without general anaesthesia. By means of the local anaesthetic used—namely, a 1 per cent. solution of novocain to which a small amount of adrenaline has been added—it is claimed that complete anaesthesia of the scalp can be obtained. Osteoplastic flaps made with the aid of an electrically driven burr or perforator and a Gigli saw are the usual means of opening the skull. The use of the high-frequency current is advocated, not merely for haemostasis, but for the removal of tumours.

Conclusion.

Mr. Cairns's valuable account of intracranial surgery is illustrated by a number of excellent skiagrams and clinical pictures. The list of references in the report is fairly extensive, but we must express regret at the almost complete omission of the names of English neurological surgeons, although these have added considerably to the literature during the past ten years.

The Antiseptic, a monthly journal of medicine and surgery issued from Madras, is about to complete the twenty-fifth year of its publication. In an essay entitled *The Antiseptic through a Quarter of a Century*, which has been prepared by the editor, the Hon. U. Rama Rau, as a supplement to the silver jubilee issue to appear in April, an account is given of the various contributions made by this periodical to the progress of medicine in India. Among these he claims the raising of the status of members of the medical profession, especially of those engaged in the subordinate medical services, the regularization of the practice of lay vaccination, the suppression of quackery, the promotion of public health legislation, and the improvement of medical education in India. He concludes by exhorting members of the medical profession in India and abroad to cast away all racial and geographical prejudices, and to work for the common interest of suffering humanity.

British Medical Journal.

SATURDAY, MARCH 2ND, 1929.

FIRST APPEARANCES IN EUROPE OF EPIDEMIC ENCEPHALITIS.

To appreciate fully the peculiar interest and significance of Professor René Cruchet's latest contribution[1] to the literature of encephalitis lethargica it is necessary to recall the first communication on the subject which this eminent French neurologist, in association with F. Moutier and A. Calmette, published in 1917 (*Bull. et. Mém. Soc. Méd. des Hôp. de Paris*, xli, 614). It was while serving in the French army as a specialist medical officer at Commercy and Verdun from September, 1915, to February, 1916, and afterwards as director of the neurological clinic in the Central Hospital at Bar-le-Duc, that Cruchet and his colleagues began to notice among the troops cases presenting symptoms of encephalo-myelitis, which did not, however, conform with those of any then known disease. A preliminary note which, in addition to a general description of the forty cases as regards onset, evolution, etc., enumerated the several clinical types observed (mental, meningo-encephalitic, convulsive, choreic, hemiplegic, cerebellar and ponto-cerebellar, bulbo-protuberential, medullary, and polyneuritic), was sent to the Société Médicale des Hôpitaux de Paris on April 1st, 1917; the note was published by the society on April 27th of that year, a few days before Professor von Economo's classic paper (Encephalitis Lethargica, *Wien. klin. Woch.*, 1917, xxx, 581) on his thirteen cases appeared in print. "Mais cette communication venait sans doute avant son heure," Professor Cruchet now writes, in his present conclusions, concerning his first effort to establish his claim. Certainly the joint note of the French observers was, at the time, strangely overlooked in favour of Economo's description of a much smaller number of cases. As Professor Achard suggests in his graceful preface to the present work, this was probably due to the fact that, while the French note described a malady with many diverse forms, the Austrian author laid emphasis upon a single, though characteristic, form of the disease, so giving the impression of "une maladie très simple dans ses symptômes." There was probably much also in the name given to the obscure disease, and the comprehensively correct, though somewhat unwieldy, term "encéphalo-myélitie subaiguë" did not strike the imagination like Economo's more arresting and more euphonious title. "L'encéphalite léthargique" (encephalitis lethargica), as Professor Achard remarks, "conquit d'emblée la faveur des cliniciens." In 1920 Professor Cruchet and his colleagues published the after-histories of some of their earlier cases; in the pamphlet under consideration, and in response to general requests, he now publishes full notes of all the cases seen between September, 1915, and July, 1917. It is a document of considerable interest from several points of view. Except for the well-described case of an English nurse, attacked while on duty at Souilly, all the 64 patients were soldiers on active service, and it is interesting to note that they constituted 3.1 per cent. of the total 2,010 cases of mental and nervous cases coming under the author's observation at the time.

It is remarkable that no series of cases comparable with that occurring in the north-west of France was reported from any other military area during the war; Cruchet thinks, however, that the disease was present on other fronts and in other armies, but that it remained undiscovered. In supporting this contention he refers to cases among ex-soldiers reported in the general literature where the primary attack occurred during military service, and also to his own acquaintance with many French war pensioners suffering from Parkinsonism whose original illness was contracted on fronts as wide apart as Morocco and the East. In this connexion we may recall to our readers' memory an article published in these columns six months ago on the possible introduction of the disease from China.[2] Reverting to the clinical narratives in the present document, it can be said that, apart from the first seven cases—concerning the diagnosis of which Professor Cruchet is himself in some doubt—the series of cases, marshalled in their original groups, shows a remarkably correct forecast of the various clinical guises which further experience has often proved the disease can assume. The occurrence of four hemiplegic cases, as reported in England by Buzzard and Greenfield,[3] may be quoted as one instance among many. These original case-histories speak for themselves, and if further evidence is required to show that the majority of patients enumerated did indeed suffer from the infection now known as encephalitis lethargica, it is provided by the summaries which have been added to each case; from these it appears that roughly one-third of the patients were reviewed as late as May, 1928, and were then found to be suffering from Parkinsonism and other forms of chronic encephalitis lethargica.

Reviewing the story as it has now been brought to light, there seems to be no doubt that, while the disease was discovered more or less simultaneously by independent pioneer workers in both France and Austria, the actual priority of reporting upon it should be credited to Professor Cruchet and his colleagues. It would probably be correct to say also that if the malady now known as encephalitis lethargica was—to modify Professor Achard's metaphor—so baptised originally in Austria, it was born in France, where it has been subsequently studied with so much care and distinction.

DE MINIMIS.

"DE minimis non curat lex," but medicine is much more condescending than the law, and its hard-working partner surgery is still less above paying attention to small miseries. "Misery" is hardly too strong a word to use in describing such troublesome conditions as ingrowing toenail, and in his British Medical Association Lecture, delivered before the Northern Counties of Scotland Branch, and published in this issue at page 383, Professor John Fraser of Edinburgh did well to discuss some of these troubles, and to tell the general practitioner how best to deal with them. People whose livelihood depends on their ability to walk and stand comfortably, equally with those whose pastimes are pedestrian, find their lives rendered troublesome, and even their morals debased, by affections of the feet. Indeed, we have known a patient driven to drink by bunions, and restored to sobriety and a subsequent blameless life by suitable operations on her first metatarsal bones. Let no one, therefore, scoff at Professor Fraser's choice of subject.

[1] *L'encéphalite épidémique. Ses origines—Les 64 premières observations connues.* Par René Cruchet. Paris: G. Doin. 1928. (5½ × 8½, pp. 134; 8 figures. 15 fr.)

[2] The Origin of Encephalitis Lethargica, *British Medical Journal*, 1928, ii, 315.

[3] *Brain*, 1919, xlii, 305.

The ten affections he deals with are all well known to orthopaedic surgeons; the conservative methods of treatment best suited to them are in general well established, and, when patients are sensible enough to carry them out perseveringly, successful. Unfortunately the surgeon often has to fight against fashion, a contest in which he is apt to come off second best. It may perhaps confirm the cynic in his pessimism to reflect on the sad backsliding which has occurred in the choice and fashion of shoes in the last hundred years. The working women of 1829 did not attempt to copy the evil habits of the idle rich of that day. To the lady of fashion of the early nineteenth century, who rode in her carriage and seldom walked, three-inch heels and pointed toes may have wrought little harm, and the workers were then content with low heels and wide toecaps, and pattens or clogs for wet weather. To-day, when many women dress in flimsy high-heeled shoes, as though they were not under the necessity of walking in all weathers to omnibus, tram, or train, the wonder is, not that some of them have foot troubles, but that so many seem to escape them.

Experts will probably differ in their estimates of the importance of flat-foot in the causation of some of the deformities described by Professor Fraser, but they will all agree that the extreme degrees of hallux valgus are generally found associated with arthritic cases of over-pronation. The syndrome denoted "march-foot" is an interesting one, and its etiology and pathology were quite obscure until *x* rays revealed the secret. Rare in this country, it was not uncommon in Germany, where, as *Fussgeschwulst*, it was well known as affecting soldiers after long marches in heavy order, or after they had been practised too assiduously in the "goose step" or parade march. At first the condition was attributed to malingering, but the presence of oedema invalidated that diagnosis. Finally, the fact that fracture was the cause of the trouble in the typical case was shown with the help of *x* rays by a French military surgeon. A controversy about which part of the metatarsus normally bears the most weight raged for a time in Prussia, but seems at last to have died of fatigue, leaving both sides unshaken.

Professor Fraser describes also Köhler's disease of the navicular bone, and refers to the Osgood-Schlatter disease and other manifestations of perverted development of small bones. The number of names of observers who have described what are often unimportant lesions or syndromes is very large indeed, and the pages of dictionaries of medical terms are overloaded with them. We are sometimes reminded of a suggestion of the late Sir Jonathan Hutchinson to call new maladies by the names of the patients in whom they were first observed. Then, as Sir Jonathan said, we should have "Mrs. Jones's leg" or "Robinson's instep," and no physician or surgeon would be tempted to seek notoriety, or perhaps immortality, from a pathological specimen or a morbid process.

SLUM PROPERTY AND ITS ABOLITION.

A good deal will be heard, in connexion with the approaching general election and after it, about the problem of the slums and the reconditioning of slum property. An admirable contribution to the practical consideration of the matter will be found in Mr. E. D. Simon's book entitled *How to Abolish the Slums*.[1] Mr. Simon is, of course, an acknowledged authority on the subject of housing, and all that he says about it may be relied upon as sane and practical, in contrast to so much that is written or spoken of a sentimental and rhetorical, or at best visionary, character. The survey offered in his present book is restricted. He does not touch upon the problem in rural areas at all. He just mentions, but does not deal with, the particular difficulties of London. He has no special regard to the circumstances and law of Scotland, beyond noting the fact that "the English worker is prepared to spend a substantially larger amount than the Scotch; he demands by tradition and custom a higher standard of housing, and is prepared to make more sacrifice to obtain it." His book, therefore, has to do almost entirely with urban communities in England and Wales outside London, and he illustrates his statements very largely by the experience of Manchester and, to a less extent, of Birmingham and other great cities. Even so, he will seem to some to have rated too high the permanence of good conditions in many post-war houses, and too low the deteriorating effect of the "slum mind" in many of the dwellers in houses which are themselves structurally decent. His own figures indicate that this may be a debasing factor of the order of from 12 to 25 per cent. in even good housing schemes. It may be held, too, that he goes unnecessarily far in demanding a separate house for each family, and does not envisage what have been called "high tenements" in their due proportion. It appears a little unreasonable that such homes, when called "flats," whether luxury or ordinary, should be more and more attractive to the well-to-do, whereas when somewhat wantonly dubbed "tenements" they should be considered improper for those who are poorer. Even the calculated stabilization of the population at about 48 millions in some twenty years from now, limiting and defining the problem as it undoubtedly does, scarcely justifies the proposition, one house, one family. Outstanding merits of Mr. Simon's book are his careful definition of terms and problems, his putting of "reconditioning" in its proper place and proportion with regard to new building, his establishment of a proper criterion of "overcrowding" as contrasted with the official standard adopted by the Registrar-General, the thoughtful, careful, and moderate statement of his case and the necessities of the situation, and his logical presentation of his general programme and suggestions with regard to rent restriction, rating readjustment, and a children's rent allowance. This book, together with that by Mr. B. S. Townroe, which was the subject of an annotation in the *Journal* of December 1st last (p. 998), should enable candidates for Parliament, and all those who are interested in public health administration and social problems, to obtain a grasp of a problem which is certain in the early future to force itself on their attention.

BERI-BERI COLUMBARUM ET HOMINUM.

IN 1897 Eijkman first observed a polyneuritis of fowls and pigeons, and demonstrated its causal relationship to decorticated rice. His discovery laid the foundations of our knowledge regarding the etiology of at least one type of disease included in the generic term "beri-beri," and led eventually to recognition of the fact that deficiency of various accessory food factors or vitamins was the primary cause of a large group of pathological conditions in man and beast. Polyneuritis columbarum is a specific form of starvation resulting from the almost complete absence of vitamin B from the food, and it may be prevented by the addition of purified vitamin B hydrochloride in no greater quantity than 2 to 2.5 parts in 1 million parts of washed polished rice. Among other pathological changes in this disease there is atrophy of the heart, in contrast with the hypertrophy of the heart characteristic of beri-beri hominum. This difference was first established by McCarrison (1919); but now, as a result of further researches,[1] he has succeeded in reproducing in pigeons the

[1] *Beri-Beri Columbarum.* By Lieut.-Colonel R. McCarrison, C.I.E., M.D., I.C.S., etc. Indian Research Memoirs, No. 10. Calcutta: Thacker, Spink and Co. 1928. (Cr. 4to, pp. v + 146; 26 figures, 7 plates.)

human type of beri-beri with characteristic hypertrophy of the heart. He holds that the elements of the disease—namely, multiple neuritis, cardiac derangement, and oedema—are all equally important and characteristic, and though there is great variety in their degree and their combination, the presence of all three constitutes the complete clinical picture of true tropical (wet) beri-beri. Current conflict regarding the causation of beri-beri turns on whether the disease is due to the action of a toxin or toxins in rice, perhaps aided by a vitamin deficiency, or whether it is due solely to deficiency of the antineuritic vitamin. McCarrison, working with a number of pigeons sufficient to provide adequate statistical data, has demonstrated that a condition of beri-beri columbarum, with all the pathological characters of human beri-beri, can be produced in pigeons by means of diets similar to those used by human sufferers from the disease, and that it can be prevented by the same means as those which prevent beri-beri hominum. The basal factor in the production of beri-beri columbarum is insufficiency, but not complete lack, of the antineuritic fraction of vitamin B. There is an optimum insufficiency of vitamin B—provided by diets of which the vitamin B value is from 20 to 50 per cent. below the minimum required for the maintenance of normal metabolism—at which beri-beri columbarum is most likely to arise. The ultimate cause of the disease, McCarrison believes, may be traced not to the negative factor of vitamin deficiency, but to the operation of a toxic agent produced in the course of a disordered metabolism determined by too little vitamin B in the food. To the operation of this toxic agent may be attributed in whole or in part the clinical and pathological manifestations of beri-beri. McCarrison believes the beri-beri columbarum which was the subject of his investigation to be equivalent to the variety of beri-beri hominum endemic in parts of the Madras Presidency, and that his experimental results confirm the view that true tropical beri-beri is due, not to toxins produced in rice by bacterial action, but to vitamin B insufficiency. Such a conclusion does not preclude the possibility that other maladies resembling beri-beri, and even given its name, may have a different etiology. McCarrison believes that the chief reason for the prevalence of beri-beri among certain rice-eating races in India lies in the fundamental poverty of the vitamin B in the whole grain of the rice available for their consumption.

BESREDKA ON IMMUNIZATION.

THE current theory of antibacterial immunization postulates as an essential element in the process the production or presence of an antibody. A considerable inroad has, however, been made into the theory of late as a result of the researches of Professor Besredka, whose recent work on immunity[1] gives a very clear account of his views and of the stages by which they were arrived at. The current theory rests on Bordet's work on haemolysins, in which he showed that the introduction of alien red blood corpuscles into the circulation is followed by the production of antibodies. It has been assumed, somewhat arbitrarily as it would seem, that a like reaction follows the introduction of bacteria into the body; but, as Besredka points out, actively proliferating and toxin-producing bacteria differ greatly from blood corpuscles, and might be expected to give rise to a different reaction; the two resemble each other in having a protein basis towards which the organism doubtless reacts in either case by elaborating lysins and coagulants, but there the resemblance ends. Besredka asserts that the production of antibody is not essential, and he has been led to propound a new theory of antibacterial immunization as the result of his experiments, among which those on anthrax infection are perhaps the most striking. The difficulty experienced in immunizing the guinea-pig against anthrax is well known; the animal has been considered to be so extremely sensitive to the virus as to preclude the possibility of immunization, a single bacillus being sufficient to induce a rapidly fatal septicaemia. But Besredka has shown that, if the skin is left out of account, the guinea-pig exhibits a complete natural immunity to the virus; if care is taken to leave the skin intact, a hundred times the lethal dose may be injected into the brain, peritoneum, or other organ and no ill effects follow. Moreover, no appearance of antibodies follows the injection. Further, he has shown that the fatal result which ensues on the injection of the skin is not due to the resulting septicaemia, since the latter is a late, almost agonal phenomenon; death must be attributed to the prior intoxication from the skin lesion. It is clear then that, if it is permissible to generalize from this particular case, the tissues of the body are of two kinds in regard to their reaction to virulent bacteria: one kind is non-receptive and the bacteria behave towards it as saprophytes, the other is receptive and enables the bacteria to proliferate and produce their toxins. Moreover, the receptive cells are not disseminated through the body, but are located in definite organs (in the skin in the case of anthrax). Hence Besredka was led to the conception of local immunization, and he found that it was perfectly feasible to establish complete immunity against anthrax in the guinea-pig by making a large number of injections of vaccine into the skin of different parts of the body or by applying it as a compress over the whole surface of the abdomen. The immunization is local but the immunity is general, because the remaining tissues of the body, other than the skin, possess a natural immunity. Immunization so induced is not associated with the appearance of antibodies, and according to Besredka the mechanism of vaccine therapy has nothing to do with antibodies. During an infection the body furnishes of itself the maximum effort of defence that is possible to it. Vaccine therapy does not cure the diseased cells, it merely protects the healthy ones. In the course of disease already present the effect of vaccines is to saturate the affinity of the receptive cells for the virus and render them incapable of reacting with them. Vaccine therapy thus aims at the prophylaxis of the healthy receptive cells; its object is to circumscribe the focus of infection by rendering the healthy cells unsuitable as a medium for a new infection. As to the cells already infected, the microbes that have invaded them are dealt with by the phagocytes.

"TOO TOO SOLID FLESH."

"I SEE no objection to stoutness, in moderation," remarked the buxom Fairy Queen in *Iolanthe*, but the usual fate of the fat affords a striking illustration of the futility of half-measures; it indicates the results of adopting a policy which is not founded on a clear comprehension of the underlying causes and on a recognition of the necessity for carefully planned action during the rest of the patient's life. Of half-measures in this field there are plenty. Educational campaigns may show that the expectation of life of the fat is much inferior to that of their lean brethren, and that the former's morbidity rate is relatively high, but such education is only of temporary value. Again, heavier members of both sexes may from time to time undergo "cures" at hydros and similar resorts suited to their fancies and purses, conceivably in the propitiatory spirit in which our mediaeval ancestors punctuated their lapses from virtue with penitential interludes. Until we give up regarding overweight as a mere incident, like a foreign body which has wandered into the eye, and begin to treat it as we would diabetes or any other deep-seated constitutional ailment with which we are familiar, our efforts are

bound to be as futile as they are irrational. This is reasoning which every senior medical student could bring forward, so close is it to the repetition of truisms; but it is quite another matter to produce carefully analysed records wherewith to drive home the argument. It is in this respect that a paper published by Dr. S. A. Holböll in *Ugeskrift for Laeger* for January 10th is of considerable value. He has investigated the subsequent careers of 100 patients treated for overweight between July 1st, 1926, and December 31st, 1927, in a hospital in Copenhagen. They were re-examined in 1928, from four months to a year and three-quarters after discharge. All the patients were women of the working classes, and most of them were admitted to hospital for complications of overweight; indeed, there were only four admitted to hospital for obesity alone. In the case of such complications as heart disease only those patients were included in this study whose cardiac symptoms were considered to be the effect rather than the cause of the overweight. It is interesting to note that by far the most common complication was osteo-arthritis deformans of the knees, found in 47 cases. Heart symptoms were present in 22 cases, flat-foot in 13, varicose veins in 15, lumbo-gluteal myalgia in 17, sciatica in 8, adiposalgia in 35, and neurasthenia in 19. More than half the number of patients were over 50 per cent. above the normal weight. The treatment employed was dietetic, and also included the administration in 85 cases of thyroidin, and in 71 cases the institution of hydrotherapy with massage. The action of the bowels was promoted in cases of constipation. The average duration of residence in hospital was about five weeks, and the average loss of weight was 20 lb. The immediate results on discharge were very satisfactory, and improvement was recorded in all the patients showing heart symptoms, in 57 of the 64 with complications affecting the lower limbs, and in 9 of the 12 cases of adiposalgia. Patients who had been admitted to hospital almost unable to move, puffing and sweating on the slightest exertion, were discharged as comparatively healthy and active human beings. Since they were still above the normal weight, they were urged to continue their dietetic regime at home. The connexion between their symptoms and their overweight was repeatedly explained to them, and they were advised to weigh themselves at regular intervals, and to obtain thyroidin from their doctors if their weight did not decline. In almost every case their doctors were notified of the results of the treatment in hospital, and were told that a further reduction of weight was desirable. In spite of all these precautions it was found that 93 of the 100 patients had gained weight, the average gain being 22 lb. In most cases the improvement achieved with regard to the complications was not maintained. Indeed, there were only 12 patients who were found on re-examination still to enjoy the improvements recorded on discharge, and many of these had only recently been discharged. Only 23 of the 100 patients had even attempted to diet themselves after discharge, and only 9 had subsequently taken thyroidin—a drug which their doctors were often unwilling to give them. Dr. Holböll's remedies for this very disappointing state of affairs include educating the patient and, in some cases, the doctor, both of whom must be taught that overweight is not merely an aesthetic blemish, but, in its advanced forms, and when complicated by circulatory disturbances, a very serious disease. His observation that only a few of his patients possessed their normal capacity for work is but another way of saying that overweight is one of the most costly complaints from which the community suffers. The picture he puts before his colleagues is vivid enough: middle-aged and elderly women of the working classes waddling into hospital under a miscellaneous burden of ailments, and sailing out again almost symptom-free, only to relapse in a few months' time. Only a few of these relapses were inevitable; the women who could not afford to diet themselves, and those who were too stupid to do so, constituted a very small minority. The kernel of Dr. Holböll's advice is to be found in the following sentence: "Efforts should be made to assure in some form or other an effective control of these patients after their discharge." Whether fat people are more self-indulgent than others is not for us to decide, but Falstaff evidently took it for granted that they are when he said to Prince Hal: "Thou seest I have more flesh than another man, and therefore more frailty."

HOSPITALS IN WESTERN AUSTRALIA.

FOR some years past the Public Health and Hospitals Department of Western Australia has undertaken increasing expenditure for medical services; whereas in 1925 the total expenditure was £172,066, in 1926 it was £185,624, and in 1927 it was £197,721. The increase has been due in part to steady extension of the hospitals, and in part to the fact that the operation of the entertainments tax has made more funds available. The system of hospital administration throughout the State is by no means uniform. The older hospitals, established in the days when the Government of the State assumed the responsibility for supplying hospital services, were placed under direct departmental administration, and the bulk of these have remained so administered till to-day. Twenty-seven hospitals are thus controlled by the department, in addition to the King Edward Memorial Hospital at Subiaco and the Wooroloo Sanatorium. The so-called public hospitals, of which there are three—namely, the Perth, the Children's, and the Fremantle—work on a different system from the rest; in them the professional work is mainly done by the honorary medical staffs, and only those persons who cannot reasonably be expected to pay for medical or surgical attention are admitted. Throughout the State, moreover, there are a number of hospitals administered by local committees, and to these and to the hospitals controlled by the department anybody may be admitted, the poor receiving medical services gratis, those of moderate means paying a small fee, and the well-to-do full fees to the doctor attending them. All types of cases are admitted to the same wards, and receive the same hospital services and care. Of recent years, while there has been increasing provision of hospitals in the newer settlements, many medium-sized institutions in the older towns have been neglected. Several of them, though perhaps adequate when they were built, are now hopelessly out of date; some are insanitary, and many are seriously short of accommodation. In general terms, the policy of the department is not to support the erection of hospitals within thirty-five to forty miles of existing hospitals; the aim is to provide settlers with reasonable hospital facilities, having in view the better roads that are and will be available, and the improvements in motor transport.

FORLANINI AND ARTIFICIAL PNEUMOTHORAX.

IN 1920 there was founded in Milan a society having for its object to honour the memory of Carlo Forlanini (1847–1918), and to promote the study of tuberculosis, and more especially tuberculosis of the lungs, in the treatment of which Forlanini did notable pioneer work. That society has now published a volume of Forlanini's collected works,[1] many of which were scattered through various journals, accessible only with difficulty at the present time. The book gives a connected account of Forlanini's researches. The first suggestion that abscess and other lesions of the lungs might advantageously be treated by means of artificial pneumothorax appears to

[1] *Scritti di Carlo Forlanini.* Scelti e Pubblicati a Cura della "Fondazione Carlo Forlanini." Bologna: L. Cappelli. 1928. (8½ roy. 8vo, pp. 1015; illustrated. L. 120.)

have been made by Dr. James Carson in a communication to the Medical Society of Liverpool in 1821. No attempt was made at the time to carry out the suggestion in practice, and it was not until the year 1882 that Forlanini proposed to substitute artificial pneumothorax for the surgical methods then on trial in the treatment of tubercle of the lungs—namely, pneumotomy and ablation. No opportunity of putting the method into practice occurred until 1890, when favourable results were obtained and reported to the International Congress held in Rome in 1894. An interesting account is given of Forlanini's first successful case—a girl of 17 in whom lung trouble had existed for two years; there were signs of a cavity in the upper part of the right lung and abundant bacilli in the sputum; the left lung was normal. The patient appears to have been completely restored to health. Forlanini was followed in 1898 by John B. Murphy, and later by Brauer and Saugmann, and the method is now practised largely throughout Europe and America. The volume is almost entirely concerned with the pathology of the lungs, and more than half of its contents deal with the subject of artificial pneumothorax and its application to tuberculous disease.

A "NATIONAL CAMPAIGN."

OUR attention has been drawn to a commercial organization registered as Oscilectron, Ltd., which heads its advertising circulars with the impressive title "National Campaign Against Rheumatism." In one of its leaflets, sent out on January 17th, 1929, this company invites sufferers from rheumatism in any form to visit with a friend "the Bristol headquarters of the National Campaign Against Rheumatism," and witness a demonstration of a machine called the "oscilectron," by which it claims to obtain "immediate results" in the treatment of "Rheumatism or one of its kindred complaints (Arthritis, Neuritis, Lumbago, Sciatica and Stiff Joints), also Flat-foot, Head Noises, and Catarrhal Deafness." It may be good business for a company, whose sole purpose seems to be the exploitation of a proprietary appliance, to adopt words that suggest some connexion with the National Campaign Against Rheumatic Diseases, of which Sir Thomas Horder is chairman. Needless to say, however, the two organizations have nothing whatever in common. The directors of Oscilectron, Ltd., are stated in the circular as: Sir T. Cato Worsfold, Bt., M.A., LL.D., S. Finklestone (British-Russian origin), and John Vielle (British). We know nothing of the other two directors, but it surprises us that a person of the standing of Sir Cato Worsfold should lend his name to such methods.

BILLROTH CENTENARY.

MEDICAL men and women in all parts of the world will honour next month the memory of the great Austrian surgeon Theodore Billroth, who was born in April, 1829. The Medical Faculty of the University of Vienna, the Vienna Academy of Science, and the Medical Society of Vienna have united to organize special centenary celebrations on April 9th and 10th in the city where Billroth practised and taught from 1867 until his death in 1894, and it is expected that the medical profession and scientific associations of many foreign countries will be represented. The idea of holding centenary celebrations originated in the small circle of those in Vienna who learnt under the pioneer of visceral surgery, but Billroth's disciples and admirers are to be found in the chairs of medicine and surgery of every country, and not only in Austria and Germany. Full particulars of the celebrations can be obtained from the Akademie der Wissenschaften in Wien (Universitaetsplatz 2, Vienna I).

SOUTH AFRICAN MEDICAL CONGRESS.

THE second Annual Meeting of the Medical Association of South Africa (British Medical Association), incorporating the twenty-third South African Medical Congress, is to be held at Port Elizabeth in the week beginning May 13th; it will be opened by His Honour A. J. P. Fourie, Administrator of the Cape Province. An official invitation to appoint delegates to the Congress has been sent to the Council of the British Medical Association, which will be glad to hear of any members who are likely to be in South Africa at the time of the Congress. Any such members are cordially invited to communicate with the Medical Secretary of the Association at the B.M.A. House, Tavistock Square, W.C.1.

INFLUENZA.

OUR conjecture that last week's total of deaths ascribed to influenza in the great towns of England and Wales would be of the order of 1,200 proved correct; the total rose from 967 to 1,241. It seems clear that in London and the north-west the maximum has now been reached, and probable that for the country as a whole the worst has been passed; the total number of notifications of pneumonia decreased from 3,898 to 3,658. There is, however, evidence in Yorkshire and the North that a further increase should be looked for, and probably also in the Midlands. The intense cold does not seem to have affected the incidence of mortality. Clinical reports still speak of the general mildness of the epidemic.

THE Council of the Royal Society, at its meeting on February 21st, recommended fifteen candidates for election into the Society. The new Fellows include Dr. John Mellanby, who holds the University Chair of Physiology at St. Thomas's Hospital, London; Dr. H. S. Raper, Brackenbury Professor of Physiology in the University of Manchester; and Dr. F. W. Twort, superintendent of the Brown Animal Institution (University of London).

THE spring course of demonstrations of specimens in the museum of the Royal College of Surgeons of England will commence on Monday, March 4th, when Mr. C. E. Shattock will demonstrate specimens illustrating diseases of the tongue and lips. On Friday, March 8th, Sir Arthur Keith will demonstrate the anatomy and pathology of diverticulitis. On March 11th and 18th Mr. Shattock will show specimens illustrating diseases of the kidneys and testis. On March 15th Sir Arthur Keith will discuss recent advances in our knowledge of the anatomy and physiology of the gall-bladder, and on March 22nd the nerve supply and movement of the colon. The demonstrations will be given in the theatre of the College in Lincoln's Inn Fields, W.C., at 5 p.m.; they are open to advanced students and medical practitioners.

THE KING.

OUR readers will have noted with pleasure the uniformly favourable tone of the announcements about the King which have appeared in the newspapers since His Majesty travelled to Craigweil House on February 9th. Although the weather has been almost as bleak on the south coast as in London, definite progress is reported, and a most encouraging sign is the increase in weight. Equally significant is the fact that His Majesty is now able to move about his room and to follow with interest the news of the day.

DERMATOLOGY AS A BRANCH OF GENERAL MEDICINE.

LETTSOMIAN LECTURE BY DR. H. W. BARBER.

THE first of three Lettsomian Lectures was delivered before the Medical Society of London on February 18th by Dr. H. W. BARBER, physician in charge of the skin department, Guy's Hospital. His general subject was "Dermatology in relation to other branches of medicine."

The Function of the Skin.

Dr. Barber began by remarking that he was satisfied that dermatology, which was once the Cinderella of medical specialties, had now come into its own; the mere reading of a modern textbook indicated how intricate a subject it had become. He hoped to show in these lectures that Erasmus Wilson was justified in saying that cutaneous medicine was a branch of general medicine of great significance and importance. The lecturer held that the study of the normal skin and the accessible mucous membranes, and the common changes that occurred in them as the result of faulty metabolism or invasion by infective organisms or toxic substances, should serve as the student's introduction to clinical medicine.

He proposed in this first lecture to consider, first, certain physiological functions of the skin which had played an important role in the progress of mankind from a primitive to a civilized state, and secondly, the morbid effects upon the skin and mucous membrane that the unnatural conditions under which the majority of civilized people were compelled to live might entail.

It was almost a truism to say that the skin was a buffer between the body as a whole and its environment. There were, however, certain points in its physiology which were insufficiently realized, and which were of profound importance in general medicine. The skin determined to a great extent the reaction of the organs of the body to external influences, such as heat, cold, and trauma. It was not too much to say that through the medium of the skin the evolution of civilized man had come about. The differentiation of the various species of animals and types of men was in some degree a question of climatic conditions. Presumably civilization dated from the time when a band of primitive men made their way northwards from the tropical zone, and on the approach of winter tried to obtain artificial warmth, first by means of underground shelters and the skins of animals, and later by discovering how to make fire.

Climate in Human Evolution.

Further development and differentiation of races, and their rise and fall, was dependent on several factors, of which climate was perhaps the most important. For work and health the best climate was one in which the mean temperature rarely fell below 38° F. or rose above 64°. Variability of temperature and weather conditions from day to day were factors of great importance. A mean temperature of 50–60° was the optimum for both physical and mental activity, which diminished rapidly when the temperature went above 65°. The localities in which such conditions favouring efficiency obtained were exactly those in which civilization had reached its maximum. Speaking on one of the most inclement nights of a severe winter, Dr. Barber still declared that the British climate was largely responsible for the position held by the Anglo-Saxon race to-day.

The temperate climate, with its frequent and moderate changes from warmth to cold, and vice versa, made for vigour of body and mind. On the other hand, the effect of the constant moist heat of the tropics and the paralysing influence of long periods of intense cold needed no demonstration. Although the invention of clothing and artificial methods of heat production had enabled man to flourish in climates which favoured his activity and progress, yet owing to the misuse of the very comforts and pleasures and labour-saving devices which his ingenuity had created, and the unnatural conditions under which a large proportion of the population lived, the effect upon man's purely animal functions had been disastrous. Dr. Barber instanced the slothful habit and gross appetite of some and the faulty diet and under-feeding of large numbers of others. Truly did a Frenchman say, "Man does not die; he kills himself." Man had created his own pathology.

Diseases of Civilization.

To anyone who surveyed the general trend of medical research and treatment during the last few years it must be obvious that there was a return to beginnings. The Egyptians, Greeks, and Romans were all cognisant of the beneficial action of sunlight and cool air on the skin, yet the value of these had only lately been rediscovered by the moderns. The very factors which enabled man to emerge from his tropical lassitude had for generations militated against his physical development. Clothing and fuel he had abused, covering his unfortunate skin, even in summer, with layer on layer of impermeable material, and he heated his houses, offices, and hotels so as to create an atmosphere more pernicious than that of the torrid zone from which he sprang. The dictates of fashion and the mistaken fear of "catching cold" had robbed the body of one of its great sources of health—namely, the exposure of the skin to light and air.

One could reasonably compare the diseases to which man living an active outdoor life under so-called primitive conditions was subject with those of animals in their wild state, and the diseases of man in so-called civilized existence with those of animals in captivity. The latter included disorders of metabolism and function which were probably unknown to primitive people and which did not occur among wild animals. Some of these appeared to have arisen within the memory of our own generation, so kaleidoscopic were the changes of disease. The more virulent infections had been succeeded by a variety of subacute or chronic conditions due to organisms which were formerly non-pathogenic and normal inhabitants of the human mucous membrane. The skin and the mucous membranes of the mouth, nasopharynx, and intestine had a natural saprophytic flora of their own; in addition to the invasion of foreign organisms leading to the production of specific diseases, their own saprophytes might, under certain conditions, become pathogenic, give rise to local conditions, and by infecting the blood stream cause morbid effects in distant organs or tissues.

The Seborrhoeic State.

The lecturer spoke of three organisms which might almost be considered normal inhabitants of the skin or mucous membrane in civilized man—namely, pityrosporon, the acne bacillus, and *Staphylococcus albus*. A predisposition to the growth of these three organisms was afforded by that morbid state of the skin usually termed seborrhoea, by which was meant an excessive or altered secretion of the sebaceous glands. He did not mean that these organisms occurred only in seborrhoeic skin, but seborrhoea was by far the commonest condition of such growth. Of all diatheses the seborrhoeic one was probably the commonest. It exemplified how a metabolic change resulting from unnatural conditions of life might produce an environment which enabled ordinarily harmless saprophytes to become parasites and produce skin diseases. The skin was not alone involved in the seborrhoeic state; the mucous membrane suffered and became likewise the prey of these particular saprophytes.

After showing photomicrographs and other illustrations of the action of the three organisms mentioned, the lecturer discussed the cutaneous manifestations of the seborrhoeic state, the thickened, gross, dirty skin, the imperfectly formed horny layers, the greasy scalp with adherent dandruff, and the dank and lifeless hair, also changes in the mucous membrane and some other manifestations, including chronic nasopharyngeal catarrh with frequent exacerbations. The seborrhoeic state being an index of faulty metabolism, it was evident that diet was a factor of paramount importance. It was easy to understand how the normal sebaceous secretion might be altered by excessive intake of fat or fat-forming foods. The best treatment, apart from dietary restrictions, was a vigorous outdoor life in a sunny climate. He believed the seborrhoeic state to be worthy of closer study than it had received. It was the basis from which conditions of far greater importance than its cutaneous manifestations arose.

Belgium.

[FROM AN OCCASIONAL CORRESPONDENT.]

A Health Insurance Scheme.

FOLLOWING on her ratification of the International Convention which was drawn up by the International Labour Office at Geneva in 1927, Belgium is now required to introduce a compulsory health insurance bill. Up to the present the practice in this country has been the subsidizing of voluntary effort—that is to say, Government grants are made to private mutual insurance societies. Now that a scheme of compulsory insurance has been rendered necessary by her acceptance of the decisions taken at Geneva in 1927, a commission has been appointed in Belgium to draft legislation for insurance against sickness and disablement.

The proposal thus elaborated may be said to have as its fundamental principle that each insured person shall become eligible for full treatment, comprising the various specialties as well as ordinary medical and surgical benefits. Every workman between the ages of 14 and 65 who receives less than 12,000 francs a year is compulsorily insured. The administration of sickness insurance is entrusted to the recognized insurance societies, the insured person retaining free choice of which society he shall join out of those approved by the Government. Insurance in respect of invalidity is effected on the same lines by federal bodies analogous to the British approved societies, which will similarly receive State approval. All these agencies will have to submit to general control and accept responsibility for providing their members with all the benefits made available by the general insurance legislation. They will be supervised by a higher council of sickness and invalidity insurance, which is to be composed of twenty-seven members appointed by Royal decree as follows: (1) seven nominated by the Government, two representing more particularly the commercial and industrial interests; (2) two actuaries; (3) three medical practitioners and three pharmacists nominated by the recognized national associations of doctors and chemists; (4) twelve delegates from the industrial insurance societies which accept the proposed law, and from the central invalidity board, membership being allocated among these bodies in proportion to the number of their members who are compulsorily insured and come within the scope of the law.

Four essential points advanced by the Belgian medical profession are: (1) there must be an absolutely free choice of doctor, specialist, and residential institution, a minimum charge being fixed in respect of payments to medical staffs as well as for maintenance; (2) arrangements for paying medical staffs shall be left to medical practitioners, who will discuss the principles involved through the agency of their own delegates to a higher committee of insurance institutions or provincial subcommittees; according to the neighbourhood, payment will be made either by contract or on an attendance basis; (3) professional secrecy must be safeguarded absolutely in the interests of the patient as well as of the doctor, but information may be given by the treating doctor to the supervising doctors; (4) the necessary control shall be entrusted to medical practitioners chosen by insurance societies in consultation with professional associations, and any disagreements be dealt with by committees on which each has equal representation.

The main feature of the Belgian scheme is that the worker is insured by his local society, and that one-quarter of the cost of his insurance is paid by him. These two factors favour financial control and enable the insured person to appreciate the value of his own contribution. In fact, since he pays his quota personally to his own society or local union, and its subsequent disposition is not hidden from him, he will be the first to object to misapplication of the funds.

Sequels of Encephalitis Lethargica.

During recent years there have been many cases of encephalitis lethargica, and the serious sequels of this infection have formed the subject of numerous investigations. Dr. Oliviers has contributed to the Belgian Society of Mental Medicine the results of his study of the mental deterioration thus brought about, and his conclusions deserve to be noted. He finds that the mental disturbances of encephalitis lethargica are more common after childhood than is generally realized, affecting some 75 per cent. of adult patients, and occurring most frequently in those predisposed by their heredity or by inherent faults of character. They appear at a considerable interval after the termination of the obvious convalescence period, and possibly after a lapse of three or four years. The mental change is nearly always associated with neurological signs, just as neurological sequels are rarely present without mental impairment. There is, however, no definite relation to be made out between the nature of either of these morbid conditions. All the varieties of mental abnormality may be met with, including depression, the lesser forms of mania, the hebephrenic-catatonic syndrome, and bradyphrenia. The different types are very seldom clearly defined, and the symptoms are remarkably variable. These mental disturbances are to be attributed to the persistence of the encephalitic virus, and the prognosis is grave. With rare exceptions the retention of these patients in a residential institution is necessary under close supervision; rigid precautions have to be taken, including the provision of special accommodation, in view of the perversity, subtlety, and unpleasant behaviour of the victims of this disease.

Prevention of Motor Accidents.

The Royal Academy of Medicine is taking up the serious problem of what can be done to deal with motor drivers who have physical disabilities, but at the moment no solution has been found. Professor Weekers suggests the following line of approach. A list should be prepared of those physical defects which are incompatible with safe motor driving. In some way or other, in conformity with our existing legislation, arrangements would be made to notify accordingly all who apply for driving licences that motor driving by any person afflicted with one of these conditions would constitute a serious offence. If, in spite of this, he continued to drive at his own risk, and an accident happened, he would automatically become liable to a heavy fine and a term of imprisonment. Under such conditions, it may be presumed, insurance companies would need no further stimulation to insist on a medical examination of those applying for accident insurance, in the same way as they do in the case of life insurance. The companies would appoint for this work medical practitioners, who would have access to specialists and would be enabled to keep under observation any candidates whose condition gave rise to doubt. In this way there would be a guarantee that persons unfit to drive were prevented from doing so.

Campaign Against Quackery.

The Belgian Medical Federation has convened a joint committee of representatives of medical practitioners, dentists, and chemists, with a view to seeing if any common action is desirable as regards charlatanism generally. This committee will be empowered to submit proposals for any alteration in the existing laws relating to the practice of the healing art which its joint wisdom indicates as being necessary. It will look out for opportunities of facilitating the growth of a system of medical jurisprudence, and will call the attention of members of the medical profession to the ways in which charlatanism can be suppressed. This committee has already undertaken a strong campaign against those varieties of quackery which inflict injury upon the general population and tend to the public discredit of the medical practitioner.

Scotland.

Voluntary Hospitals in Scotland.

AT a meeting of the Scottish Regional Committee of the British Hospitals Association, held in Glasgow on February 20th, the position of the voluntary hospitals as affected by the proposals of the Local Government (Scotland) Bill was discussed. Colonel John A. Roxburgh, chairman of the governors of the Western Infirmary, Glasgow, presided. He recalled that at the last meeting of the committee in December, 1927, it was agreed to set up local committees in the five regions into which Scotland was divided, in

order to consider the possibility of co-operation between statutory authorities and the voluntary hospitals, and also to approach the Secretary of State for Scotland in regard to his views on the subject of co-operation between hospital authorities. The Secretary of State had appointed a liaison committee for the purpose of keeping his department in touch with voluntary hospital opinion, and assisting the voluntary hospitals in regard to regional difficulties. Colonel D. J. Mackintosh, medical superintendent of the Western Infirmary, Glasgow, who is a member of the liaison committee, stated that this committee consisted of the representatives of voluntary hospitals in different areas, and the committee had been actively engaged in drafting proposals with reference to the Local Government (Scotland) Bill. Under this bill the Poor Law hospitals would be transferred to the town and county councils. A proposed amendment to the bill had been put forward by the Corporation of Glasgow to empower local authorities to remove hospital services entirely from the Poor Law, and to provide hospital treatment for all kinds of sickness, which was exactly the position in England and Wales. The liaison committee, representing voluntary hospitals, could not recognize discrimination in quality of hospital treatment between paupers and non-paupers, and it considered that the only way to avoid this was to remove hospital treatment entirely from the Poor Law by conferring on the Scottish authorities the same general power as would be possessed by the English authorities. It could not contemplate the growth of a general hospital service which would prevent complete co-operation with the voluntary hospitals. The removal of the hospital services from the Poor Law would, however, have to be done under conditions that would provide full safeguards for the voluntary hospitals. Consequently, as the result of meetings between the liaison committee and the Department of Health, a new clause had been drafted with a view to removing the Poor Law stigma from hospital services, and the Scottish voluntary hospitals would secure provisions that substantially safeguarded their future place in the scheme of hospital services. The voluntary hospitals would require to be active and far-seeing, and much would depend upon their machinery, local and central, for ensuring co-operation among themselves and with the public authorities. The department's view was that much of what was proposed could be achieved by administrative action without the necessity for legislation. The position was worthy of the most careful study by the Scottish Regional Committee of the Hospitals Association, and the liaison committee could be effective only if it had behind it an informed body of opinion. The chairman said that the area committees were to make their opinions known to the Department of Health through the members of the liaison committee representing them, and it had to be decided what was the best way of keeping those members of the liaison committee informed of the opinions of their particular areas. He thought that the Regional Committee of the British Hospitals Association was the best body in Scotland to concentrate the opinions of the hospitals, and many questions were bound to arise regarding which the considered opinions of the hospitals in Scotland would be very valuable. In the course of discussion it was pointed out that it would be desirable to have the views of the areas co-ordinated before they went forward to the liaison committee, for it would be unfortunate if different views were put forward from various areas on any particular subject. In order to avoid this, it was suggested that periodic meetings of the Regional Committee should be held to consider the reports of the area committees. It was generally agreed that the proposed amendments to the bill were satisfactory.

Crichton Royal Institution, Dumfries.

The eighty-ninth annual report of the Crichton Royal Institution, Dumfries, for the year 1928 has just been issued. Dr. C. C. Easterbrook, physician-superintendent of the institution, in his report states that the number of patients on the register at the end of the year was 1,043, including 484 men and 559 women. During the year there had been 344 admissions, 216 discharges, and 75 deaths, and the total number of cases under treatment during the year had been 1,334, with an average daily number of 1019. Of the 1,043 patients, 746 were certified, while the voluntary patients at the end of the year numbered 297. The number of voluntary cases under treatment during the year was 459, the highest number hitherto recorded. The number of private patients, certified and voluntary, at the end of the year was 694. With regard to the forms of mental disorder, the chief were, as usual, the constitutional psychoses, such as melancholia (57 cases), confusion (36), dementia (30), paraphrenia (30), mania (28), dipsomania (11), and epileptic psychosis, neurasthenia, hypochondria, hysteria, and choreic psychosis in smaller numbers. There were also 15 cases of congenital psychoses and 10 cases of organic psychoses, including general paralysis 5, encephalitis lethargica 2, cerebral apoplexy 2, and progressive muscular atrophy 1. Of the 216 discharged, 146 were voluntary patients and 70 were certified. Among the voluntary cases the recovery rate was 25.5 per cent. of the number admitted, and among the certified cases 23.5 per cent. The forms of mental disorder from which recovery took place were chiefly melancholia, confusion, mania, and delusion, and the total duration of the illness in recovered cases was less than half a year in 36 per cent., up to two years in 39 per cent., and over two years in 25 per cent. Of the 75 patients who died, 59 were certified and 16 were voluntary cases, the death rate being 7.3 per cent. of the average daily number. The chief causes of death were cardiac disease and arterio-sclerosis in 27 per cent., pulmonary tuberculosis in 13 per cent., pneumonia in 11 per cent., exhaustion in 9 per cent., apoplexy and senility each in 8 per cent., and general paralysis in 6 per cent. The mean age at death was 60 years. A hospice or new reception hospital and infirmary was occupied towards the end of the year. An arts and crafts pavilion had been erected early in the year, and was opened in May, with the object of improving the previous arrangements for occupational therapy. In this department classes of two hours' duration are held for patients who are interested in handicrafts.

Victoria Infirmary, Glasgow.

The forty-first annual meeting of the Court of Contributors of the Victoria Infirmary, Glasgow, was held in the Merchants' House on February 15th. Lord Provost Sir David Mason presided, and said that the governors of the Infirmary had shown great enterprise and wisdom in adding recently a new wing. This additional accommodation had been justified by the fact that the 6,580 patients treated during 1928 showed an increase of 1,161 as compared with those of the previous year. The desire shown by some of the patients to contribute in return for benefits received was indicated by the fact that £1,220 had been given by patients during 1928. It had been necessary to draw a sum of £22,464 from capital account in order to meet the extension schemes, and the revenue had been insufficient to meet the cost of maintenance to the extent of £8,835. He was pleased to observe that contributions from employees, which had amounted to £11,454, showed an increase of nearly £400 over those of the previous year. He thought that an appeal for funds should be made in outside districts served by the institution, in view of the fact that 1,671 of the patients had come from outside the city. Mr. William Gray, chairman of the governors, in seconding the report, mentioned that over £60,000 had been received by the three large infirmaries of the city in the past year from employees in public works. This was obtained under a system by which one penny in the pound was deducted from the wages as a contribution to hospitals, and he thought that this scheme could be advantageously extended to warehouses, offices, and shops. If the citizens could generally see their way to contribute one penny for each pound of income, it would not be necessary to make the urgent appeals which emanated every year from the hospitals. The question was raised as to whether the hospitals could secure repayment in connexion with road accidents, because in such cases less than one-tenth of the amount expended by the voluntary hospitals on such patients was returned to them. The chairman replied that an Act of Parliament would be required to deal with the situation, and it would be impossible to get one through during the life of the present Parliament. Action on this matter was being taken, however, both by the hospitals in Glasgow and by the British Hospitals Association.

Aberdeen Royal Infirmary.

The annual meeting of the Aberdeen Royal Infirmary contributors was held on February 15th, with Sheriff Dallas in the chair, when the 189th annual report was submitted. The total number of patients admitted in the past year had been 31,115, an increase of 2,647 over those admitted in 1927. The year closed with a surplus of £1,600, including £365 derived from work done by patients in the handicraft school of the institution. The chairman remarked that renewed interest was being taken in radium, of which for a number of years past the Infirmary had had a loan of a quantity from the Medical Research Council. The directors had been considering the establishment of a volunteer blood transfusion service, and he hoped that a good response would be made to their appeal for volunteers.

Maternity Home at Stirling.

A maternity home for Stirling district, which adjoins and forms part of the new Royal Infirmary of Stirling, recently opened at Livilands, was formally opened on February 15th by Mr. W. G. Gardiner, vice-president of the Infirmary. The home has accommodation for 20 beds, and is situated immediately to the west of the Infirmary. It includes an operating theatre and a large summer-house for mothers in the convalescent stage. Provision has also been made for carrying out ante-natal clinics in connexion with the hospital. The maternity home has been jointly provided by Stirling Town Council, Stirling County Council, and the directors of the Infirmary.

England and Wales.

Health Conditions in the Welsh Coalfields.

On *a priori* grounds it might be assumed that the depression in the coal-mining industry would be correlated with a deterioration in the physical and mental condition of the mining population; indeed, the view is widely prevalent that such deterioration is actually taking place. Some confirmation of the general impression is provided in a report* of a first-hand investigation conducted by Sir Arthur Lowry and Dr. James Pearse, both of the Ministry of Health, into the conditions of the inhabitants of the coal-mining districts of South Wales and Monmouthshire, though here and there in their report are patches of an unaccountable brightness. For example, the general death rates in the regions under survey showed no variations indicating the prevalence of conditions specially injurious to health. Furthermore, there has been no unusual mortality from epidemic diseases. On the other hand, in the administrative counties of Glamorgan, Monmouth, and Merthyr county boroughs the infantile mortality rate for 1927 is higher than for 1926, and the rates each year since 1920 compare unfavourably in their general tendency with those for the whole of the country. Thus, the rate in England and Wales in 1920 was 80, and in 1926 and 1927 it was 70. In Glamorgan, the rates for the same years were respectively 90, 76, and 86; in Monmouth they were 88, 66, and 87; in Merthyr county borough they were 83, 84, and 105. Complete figures for 1928 are not yet available, but in each of the counties the rates for the first nine months of 1928 are lower than for the corresponding period in 1927. It is interesting to note that no obvious growth in the prevalence of tuberculosis, a disease to which resistance is decreased by insufficient or improper feeding, has impressed itself on the district medical officers of health or on those responsible for tuberculosis administration. The death rates from pulmonary tuberculosis in 1927 are somewhat higher than in 1926 (in Glamorgan, Monmouth, and Merthyr county boroughs the rates for 1926 and 1927 respectively are 777 and 856, 572 and 611, and 682 and 705, the figures representing death rates per million of population). The figures for non-pulmonary tuberculosis, on the other hand, show a marked decline as compared with those of the earlier years. The only deficiency disease which appears to have increased is rickets. As this disease till recently has not been common in South Wales and Monmouth its occurrence as a fresh development is rightly regarded as significant of deficiency in the quality, if not the quantity, of the diet of the child population. No indication was found of obvious and widespread deterioration of physique in the population as a whole, except that in some areas women, especially the mothers of young children, suffered to an unusual extent from languor and anaemia. There is also some evidence of loss of tone and persistence of debility after illness in the older men, and men long unemployed who have not been actually ill find difficulty in the mere physical effort of resuming work. The diet in the households of unemployed men was found to comprise little beyond white bread, butter or margarine, potatoes, sugar, jam, tea, and bacon in limited quantities. Meat was seldom eaten except in very small amounts on Sunday; fresh milk was not seen except when supplied from a welfare clinic; fresh vegetables, other than potatoes, were rare. Though such diet, according to accepted canons, is unsuitable for the maintenance of health over any prolonged period, especially the health of young children and nursing mothers, the investigators have to record that they discovered no widespread manifestation of impaired health which could be attributed to insufficiency of nourishment. Apart from diet another factor which must tend to impair physical condition is insufficiency of proper clothing and footwear. In the houses visited the investigators frequently found the bedclothing and underclothing far from adequate, and the boots not enough for the school children, to say nothing of the adults and infants. These, then, were the material and physical facts of the situation observed by Sir Arthur Lowry and Dr. Pearse. They make some reference, however, to certain of its less tangible features which may, in the long run, be even more significant for evil than the hardship caused by deficiency in the necessaries of life. Above all, they record the demoralization, the depression, and the listlessness produced by long-continued idleness. A large number of the unemployed have not worked in a mine since 1921, while many men have been idle since May, 1926. Work, it appears, is needed rather than food or clothing. "The present position," it is suggested, "arises from the fact that there are many more miners in the area than can ever find work in the mines or in other industries in the locality." It is to the promotion of the transference of the surplus miners as rapidly as possible to work elsewhere that any additional funds for the relief of miners and their families can best be allocated.

Noise and Health.

A Chadwick public lecture was delivered in the University Hall, Gordon Square, W.C., on February 21st, by Dr. Dan McKenzie, who took as his subject "Noise and the public health." Sir William Collins was in the chair. Dr. McKenzie said that modern civilization was attended by various serious drawbacks, among them being ugliness, which was presented to both the eye and ear. Ugliness to the ear was noise; there were other points of view, not necessarily the same as the physicist's, from which noise may be regarded. Any sound that disturbed repose was noise, which startled and exhausted the human nervous system. The great increase of industrial noises in workshops and factories was acknowledged to have a bad effect on those who worked in them; efforts had been made to reduce the hurtful sounds and the exhaustion they produced. Domestic noise was another affliction of modern life largely produced by street and highway traffic, and little had been done to minimize it. The lecturer proceeded to describe the actual effects of industrial and domestic noises on public health, and discussed the question "Has the increase of noise any influence in the increase of mental disorders?" He lamented the dying down of Government interest in the trouble. Cessation of activity had been attributed to difficulty in concocting a definition of noise. A definition was needed, no doubt, to prevent undue interference with industry. Fifty years ago an English Government had contrived to legislate against insanitary dwellings without any definition to speak of, the only description being that

local authorities were empowered to condemn any premises in "such a state" as to be a nuisance or injurious to health; subsequent juridical rulings had shown that it was only necessary for public health purposes to prove interference with "personal comfort." This was what noise did, after all. The lecturer suggested: (1) That "zones of silence" during hours of silence should be demarcated by police or public health authorities. (2) That the streets in front of schools, colleges, hospitals, and nursing homes should be paved with rubber blocks. (3) That the size, weight, and speed of motor lorries should be reduced. (4) That heavy goods should be relegated entirely to the railways for transit. Dr. McKenzie concluded by reading a letter from a patient in a hospital complaining bitterly of the noises, not outside, but inside the hospital; he added that after inquiry he had found the complaints to be true for all hospitals. They were much too noisy, and recovery of the sick within their wards was interfered with by neglect of a primary rule of treatment. He appealed to all hospital authorities to go into this matter with their nursing staffs. They would be astonished and humiliated by the result of their inquiries. Reform was needed in the matter of subjection of invalids to noise, and reform, like charity, should begin at home. Gramophone records were used to illustrate various types of objectionable mechanical sounds and human cries. It is announced that the next Chadwick public lecture will be delivered on March 11th at 8 p.m. in the Lecture Hall of the Royal Society of Arts, John Street, Adelphi, when Mr. Mowlem Burt will show and explain a cinema film of Imperial Chemical House, and will describe the making of a modern building. Future lectures will deal with engineering as applied to health and civilization, and health in West Africa. Further particulars may be obtained from the secretary at the offices of the Chadwick Trust, 204, Abbey House, Westminster, S.W.1.

Courses in Psychiatry at the Maudsley Hospital.

The second part of the twelfth course of lectures and practical demonstrations for the diploma in psychological medicine will be held at the Maudsley Hospital, Denmark Hill, S.E.5, on various afternoons during March, April, and May. Six lectures on the practical aspects of mental deficiency will be given on Tuesdays, at 2.30 p.m., by Dr. F. C. Shrubsall, commencing on March 5th and omitting April 2nd. A series of eight lectures on morbid psychology, by Dr. Edward Mapother, will begin on March 6th, and be continued on the following Wednesdays. Dr. A. A. W. Petrie will deliver three lectures on therapeutics, on Tuesdays, commencing March 26th and omitting April 2nd. Of twelve clinical demonstrations in neurology Dr. F. M. R. Walshe will give six, on Thursdays from March 7th and omitting March 28th, at the National Hospital for Paralysis, Queen Square; Dr. F. Golla will give the remainder on Thursdays, at the Hospital for Paralysis and Epilepsy, Maida Vale, the first being on April 25th. Eight lectures on the psychoneuroses will be delivered on Mondays by Dr. Bernard Hart from April 29th, omitting May 20th. Six lectures on crime and insanity will be given by Dr. W. Norwood East on Tuesdays, from April 23rd, and six demonstrations in clinical psychiatry by Dr. Mapother on Wednesdays, from April 24th. The pathology of mental diseases will be dealt with in four lectures by Dr. F. Golla, followed by four demonstrations in pathology of the central nervous system, by Dr. Charles Geary; these will take place on Fridays, the first being on May 10th. Four lectures on the legal relationships of insanity, and treatment, will be delivered by Dr. C. Hubert Bond on Fridays, from May 10th, and Mr. Fraser Moore will lecture twice on the abnormalities of the fundus oculi—namely, on Mondays, April 15th and 22nd. Two demonstrations in laboratory methods will be given by Mr. S. A. Mann on Tuesdays, May 7th and 14th; these will include the examination of the blood and cerebro-spinal fluid. The fee for the combined course is ten guineas, and inquiries should be addressed to the director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5. In addition to the special lectures and demonstrations mentioned there are a limited number of appointments as clinical assistants available at the hospital. Service in this capacity, whether whole-time or part-time, is recognized by the various examining bodies as constituting the clinical experience required by the regulations for the diploma. Inquiries in this respect should be made to the medical superintendent of the hospital.

Sun-ray Treatment at Torquay.

Professor Leonard Hill, on February 20th, opened a "sun-lounge" at Torquay, which has been established by the municipal authorities. The new lounge is ninety-five feet long and faces due south, with a view of Tor Bay; the walls and roof are made of vita-glass. Professor Hill emphasized the importance of infants and children receiving as much sunshine and open air as possible, and commented sternly on the folly of allowing such a high content of dust to exist in most houses, as was shown to be the case when sunbeams illuminated the particles. He recalled the value of ultra-violet light in destroying ordinary bacteria, and reminded his audience that these rays could be collected from the sunshine, as well as from the sun. The necessity for paying attention to ventilation in addition to light was another point stressed by him.

Ireland.

National Health Insurance.

A REPORT on the administration of national health insurance covering the period from April 1st, 1921, to March 31st, 1928, has been issued by the Minister for Local Government and Public Health. The figure of 701,882, representing the total number of insured persons at December 31st, 1922, was made up of 386,251 persons resident in the Saorstat Eireann, 310,094 persons resident in Northern Ireland, and 5,537 persons resident in Great Britain who were "stray" members of societies or branches approved only for operation in Ireland. In the Free State in 1924 there were 435,753 insured men and women; in 1925, 466,339; in 1926, 481,785; and in 1927, 492,594. The figures show a gradual increase in the membership of societies, most likely due to the fact that the number of new entrants and of re-entrants has not been offset by the number of members who have ceased to contribute, and who, but for the operation of the Prolongation of Insurance Act, would have been automatically excised from the membership registers. Since 1923 there has been a steady increase in the amounts paid in benefit. Examination disclosed cases of excessive expenditure. The figures for sickness, disablement, and maternity benefits, taken together for each year, are as follows: 1923, £406,704; 1924, £444,274; 1925, £458,318; 1926, £530,914; 1927, £628,498. Although this increase is partly accounted for by the increase in cash benefits paid by some societies, it is feared that at least some portion of it is attributable to payments made to persons who are not genuinely incapacitated. The amounts issued to societies during the years 1921 to 1927 to pay the costs of benefits and defray the expenses of administration in respect of their members were: 1921, £930,380 (all Ireland); 1922, £593,282 (all Ireland to February 28th, 1922, Free State only for remainder of year); 1923, £479,949 (Free State); 1924, £499,720 (Free State); 1925, £521,117 (Free State); 1926, £605,577 (Free State); 1927, £712,968 (Free State). The comparatively large increases in the years 1926 and 1927 are no doubt partly due to the additional benefits which, as the result of the valuation of approved societies at December 31st, 1923, became available from July, 1926. It is thought that the prolonged period of unemployment, with its consequent effect on the vitality of insured persons, has also contributed to the increase.

Measles in County Fermanagh.

At a recent meeting of the Fermanagh Regional Education Committee, Dr. W. A. Dickson, school medical officer for the county, said he thought the members of that committee and of the subcommittees could help him by circulating a little common-sense knowledge among the people. When an epidemic of measles started many parents were of opinion that if their children caught the infection they would really be better off than if they escaped this dis-

altogether when they were young. The fact was that people were not supposed to get disease at any age, and a child who never had measles was better physically than a child who had. People living in the country knew that when there was an infectious disease in the house it was their duty to warn the proper authorities and to isolate the patient, but as a rule neither of these precautions was taken. Milk should not be sent to the creamery from a house in which there was infection, but from lack of ordinary precautionary measures infectious diseases spread rapidly. There were at present 600 or 700 cases of measles in the county, and he thought the number was increasing.

Immunization Against Diphtheria.

In a report to the Dundalk Health Board on the diphtheria immunization scheme which has been in force in Dundalk for some months, Dr. Musgrave stated that 750 children had been immunized. He referred to a great deal of loose talk which was calculated to undermine the confidence of the people in the effectiveness of the work, and stated that there was now no doubt as to the worth of the protection afforded to nine children out of ten; parents or guardians who were wise would not withhold this *nine to* one chance. The committee decided to start another campaign in August, and to provide free medical treatment for the children of poor parents.

Correspondence.

ENLARGEMENT OF THE PROSTATE.

SIR,—The addresses on enlarged prostate by Mr. Nitch and Mr. Grey Turner, and the criticisms on these now appearing in the *Journal*, have raised several points of great importance to surgeons dealing with this class of case, and I should like to add some remarks on the results of my own experience.

Mr. Turner emphasizes a dictum laid down by Sir Henry Thompson to the effect that enlargement of the prostate of such a degree as to give rise to symptoms demanding treatment does not occur before the age of 50, and quotes his own experience of over thirty years in support of it. May I venture to question the truth of this dictum.

In March, 1915, I saw a man, aged 45, who had had prostatic symptoms for at least a year. He had frequency of micturition, difficulty in starting the act, and diminution of the stream; there were two and a half ounces of residual urine. The muscular wall of the bladder was hypertrophied. A trilobed intravesical prostatic growth weighing three drachms was enucleated with complete relief of his symptoms. In February, 1926, I saw a patient, aged 47, with haematuria and dysuria of two years' duration. I removed an adenomatous prostate, weighing two and a half ounces, which shelled out easily. In January, 1925, in a man aged 47, I removed a portion of the prostate which projected upwards from the floor of the urethra close to its internal opening. The polypoid projection was half an inch long and about one-eighth of an inch thick; on section it showed adenomatous tissue with papillary growth into intracystic spaces. When seen a year and a half later the patient was quite well. In May, 1926, I saw a man, aged 45, with carcinoma of the prostate; an unsuccessful attempt was made elsewhere to remove it. The patient died within a year with large masses of growth in his pelvis Some years ago I saw a patient, aged 47, die from uraemia, the result of prolonged and neglected back pressure from an enlarged prostate. These cases demonstrate that it is unsafe to exclude enlargement of the prostate in a case of urinary symptoms in a man under 50 years of age.

I agree with Mr. Turner that the patient may present himself suffering from symptoms suggestive of gastric trouble. Some months ago I saw a patient with supposed carcinoma of the stomach in which *x* rays showed an hour-glass contraction. On examination I found a greatly distended bladder. Treatment was of no avail, and at his death I obtained permission to examine the stomach and the kidneys. The stomach was perfectly normal, but the ureters were dilated and the kidneys in a state of hydronephrosis from back pressure.

Mr. Nitch has evidently not had much experience of the indwelling catheter when he says that its use "is practically restricted to cases with slight renal deficiency or chronic urinary retention, for it cannot be employed when the bladder or kidneys are infected or when the prostate is bleeding." For cases in which clots are liable to block the lumen the catheter is, of course, useless, but my experience is that practically the only other contra-indication to its use is the discomfort it produces in quite a small proportion of patients. I look upon the indwelling catheter as one of the most life-saving measures at the disposal of the urologist, and every patient under my care is treated by this method of decompression until carefully conducted blood and urinary tests show that it is reasonably safe to operate. During this time the bladder is irrigated daily. I have seen many patients brought back apparently from the brink of the grave by this simple procedure, which any practitioner can carry out.

A man, aged 64, with twelve ounces of residual urine, when admitted to a nursing home for operation looked ill and anaemic, refused food, had a foul tongue, and suffered from nausea. His pulse was irregular and intermittent. A catheter was tied in, but he could not tolerate it, and regular catheterization with irrigation was substituted. His blood urea at this stage was 146 mg. per 100 c.cm. He continued to go downhill and at the end of a few days I urged him to make another attempt to retain the catheter. He consented, and the effect was nothing short of magical. In the short space of a week his tongue cleared, his appetite improved, and his pulse became steady and regular. On the eighth day his blood urea was found to have fallen from 146 to 40 mg. per 100 c.cm. Meanwhile the specific gravity of the urine began to rise and the quantity to diminish. He passed successfully through a prostatectomy and is living and well more than a year later.

In another patient, a man aged 70, with no other treatment than the tied-in catheter and irrigation, the blood urea fell in twelve days from 102 to 47 mg. per 100 c.cm. and prostatectomy was successfully undertaken.

A man, aged 62, was admitted to a nursing home with fifteen ounces of residual urine and a blood urea figure of 353 mg. per 100 c.cm. A thick deposit of pus, settling like bismuth to the bottom of the vessel, was present in his urine. He had hiccup and a tendency to vomit in the morning. A catheter was tied in. The blood urea fell from 353 to 240 in one week and his condition began to improve. In two months, during which time he was treated by the indwelling catheter and daily irrigation, the blood urea fell to 72. This was the best that could be done, and I then suggested suprapubic drainage. He preferred the catheter, and is going about to-day, six months after I first saw him, with an indwelling catheter, to which he has attached a stopcock, and looks the picture of health. Whether he will ever be fit for operation is a question, but he exemplifies the beneficial effects of the indwelling catheter. The catheter was taken out for a few days to try the effect, but the patient's temperature went up and uraemic symptoms developed at once; these ceased entirely on replacing the catheter.

I have in my wards at present a man, aged 58, who was admitted with uraemic symptoms and a septic bladder, the result of enlarged prostate. His blood urea was 253 mg. per 100 c.cm. With the indwelling catheter and irrigation his blood urea fell in the first week to 124 and in the second to 68. He is still under treatment, and I have hopes that he may yet be fit to undergo prostatectomy. I do not deny the benefits resulting from suprapubic drainage, but I am satisfied that in a large proportion of cases it can be replaced by the simple procedure of tying in a catheter.

As to operative technique, there is no question in my mind that Thomson-Walker's operation is an ideal one, and I have often performed it. I am, however, satisfied that a less elaborate procedure will produce good results. The operation takes longer than the old operation of Freyer, and personally I have not had a sufficient improvement in my results to warrant me in performing it as a routine. I am quite willing to admit that this may be due to my faulty technique, but I do think it is a severe measure, at any rate for the class of case I frequently meet with. My policy is to get the patient back to bed as quickly as possible, and I have not had undue trouble with haemorrhage or subsequent obstruction. On three or four occasions, it is true, I have had to deal with a diaphragm which formed between the prostatic cavity and the bladder, but this can be prevented at the time of operating by clamping the posterior lip of the septum and dividing it, a detail which takes about a minute to perform. I always use gloves, and after a trial of enucleation without placing the finger in the rectum, I have gone back to the older procedure because it steadies the prostate and renders the operation easier. Like Mr. Ralphs I use

two gloves on the left hand, one of which is removed at the proper time, and I really cannot see how, with ordinary care, any increased risk of sepsis can result from a finger in the rectum. I cannot endorse Mr. Irwin's objection to the gloved finger in the bladder. I dare say that I have many times failed to unearth minute "prostatic relics," but I wonder if they are so important as his letter seems to suggest.

After any operation for removal of the prostate, however conducted, there must remain the cavity vacated by the prostate with a raw surface bathed with septic material. The risk of absorption from such a surface must remain till it is at least covered by healthy granulations. To reach this cavity and drain it I have suggested and carried out a simple operation, the details of which will shortly appear. A tube introduced from the perineum through the ischio-rectal fossa, and passed through the sheath of the prostate, gives easy access to this cavity, and may render its drainage and cleansing less difficult to accomplish.

In making these few remarks I disclaim any intention of decrying any procedure that has for its object the reduction of the risks of the operation of prostatectomy or the morbidity following it. In all humility I may claim to have had a long and varied experience of different methods, and, having outlined my own views, I am ready and willing to lend a sympathetic ear to any suggestion that may improve my results.—I am, etc.,

Belfast, Feb. 18th. ANDREW FULLERTON.

VACCINATION IN THE LIGHT OF RECENT EXPERIENCE.

SIR,—In view of the suggestion in Dr. Goodall's letter in the *British Medical Journal* of February 16th (p. 319) that "alastrim" may not prove to be so stable a variant of small-pox as some of the speakers at the recent meeting of the Section of Epidemiology of the Royal Society of Medicine supposed, it may be of interest to record the fact that of the various outbreaks of this disease which I have had occasion to investigate officially, the earliest—that which I saw at Cambridge in 1903—was, as Dr. Goodall notes, of a much more severe type than is met with at the present time. Thus, of the 154 recorded cases at Cambridge no fewer than 15 died—a case mortality of 9.76; whereas nowadays deaths from "alastrim" are but rarely met with. Yet in many respects this outbreak differed markedly from the "textbook" types of small-pox, especially as regards the nature, method of appearance, and distribution of the rash.

Personally, as stated in my "Report on the relationship of small-pox and alastrim,"[1] I still think that "in special circumstances, various stages of varioloid disease may originate between that type to which the name of alastrim (or, in South Africa, amaas) has been given, and that which, in this country, is ordinarily regarded as typical small-pox." But definite relationship of these variants to small-pox is demonstrated by the protection afforded by previous vaccination, although the extent of such protection appears to differ somewhat according to the particular variant of small-pox under observation.—I am, etc.,

London, N.W.3, Feb. 16th. S. MONCKTON COPEMAN.

SIR,—Dr. E. W. Goodall's letter in the *Journal* of February 16th (p. 319) illustrates the confusion which results from the present method of presenting small-pox statistics. Under the name small-pox are included two forms of disease—namely, (*a*) variola major, with a case mortality which varies, but is often high and may reach 50 per cent. or more; (*b*) the fixed variant of small-pox known as alastrim (synonyms—mild small-pox, para-small-pox, amaas), the case mortality of which never varies; it is always *nil*. That is to say, the number of persons who die in the course of the disease is about the same per 1,000 cases as the number of deaths per month per 1,000 of the population from which they are segregated.

It is obvious that in any country in which these two forms of disease prevail, whether in the *same or in* different localities during any year, the case mortality for all cases of "small-pox" for that year will depend on (*a*) the case mortality of the major small-pox prevalent, and (*b*) the relative numbers of cases of major small-pox and its fixed variant alastrim. It is also clear that the figure arrived at by this method may be anything from *nil* to 50 per cent. or more. If the present method of collecting and presenting the small-pox statistics of this country had been specially devised with the malicious intention of causing the confusion now generally prevalent in regard to types and mortalities of small-pox, it could not have been more completely successful.

Dr. Goodall suggests that "it would be a crucial test for those who believe 'alastrim' to be quite a different disease from small-pox, to place cases of each disease together in the same ward of a hospital to observe whether patients suffering from the one became infected by the other." Since vaccinia protects against small-pox for a number of years, and against alastrim for a greater number of years on an average, and since small-pox protects against vaccinia for a number of years and alastrim protects against vaccinia for a number of *months*, it is reasonable to suppose that small-pox and alastrim would confer immunity each against the other, small-pox possibly for a longer period against alastrim than alastrim against small-pox. If this is so, Dr. Goodall's "crucial" experiment would give a negative result, but that would not affect the position of alastrim as a fixed or stable variant of small-pox. If the same experiment were carried out with patients suffering from small-pox and vaccinia the result would certainly be negative, but it would be a very serious matter indeed for those who, like myself, are advocates of vaccination, if this result meant that vaccinia is not fixed or stable.—I am, etc.,

Town Hall, Hornsey, N., Feb. 16th. R. P. GARROW.

ORAL ADMINISTRATION OF PITUITARY GLAND.

SIR,—For some time there has been discussion as to the efficacy of whole gland pituitary given by the mouth, it being generally held that during the process of digestion the active substances of the gland are rendered inert, and therefore the administration per os is quite useless. However, during the last five years I have been able to watch a number of cases treated by the oral administration of pituitary whole gland, and feel quite convinced that pituitary does act by this method. I append a few brief details.

Case 1.—Woman, aged 40, who suffered from adiposis dolorosa. She was so weak that she could hardly walk into the consulting room at hospital. Amenorrhoea had been present for nearly two years and also marked depression. Pituitary whole gland was given to her morning and evening. She took in all five grains daily. In a short time her strength came back, she was able to perform all her ordinary duties without feeling tired or being in any way fatigued, and menstruation was normally re-established.

Case 2.—Girl, aged 9 years, who had suffered from chronic constipation of many years' duration. The bowels were open about once in eight days. She looked very ill, and was depressed. X-ray examination showed an atonic descending colon and sigmoid. All medicines failed and she was given pituitary whole gland, ½ grain thrice daily for nine months. The bowels moved at first once every two or three days, but after two months' treatment almost every day. She developed much more vigour, looked well and lost her depression. After nine months the pituitary was discontinued and the bowels have remained practically normal since, and only occasionally she takes pituitary for a day or two at a time. At present she is in splendid health.

Case 3.—A boy, aged 4 years, who suffered from chronic constipation of a similar nature to the above, was treated in the same manner, and Dr. Robertson, who looked after him, told me that the result had been quite successful, the bowels now opening normally, nearly every day.

Case 4.—Girl, aged 12 years, suffering from pituitary adiposity, was given a quarter of a grain of thyroid twice daily, and two grains of pituitary thrice daily, at the Royal Waterloo Hospital. In just over a month she lost nearly a stone in weight and looked well in every way. We noticed, however, the tendency of the systolic blood pressure to mount upwards when larger doses of pituitary whole gland were given, and we ultimately reduced the dose to three grains daily. The greatest amount taken in two or four hours was nine grains. The action on the blood pressure is very useful in treatment of the next case.

Case 5.—A physician, who had always suffered from low blood pressure, the systolic being generally in the neighbourhood of 100 to 106 mm., and rarely above 110 mm., felt distinct

[1] Appendix to the Report of the Chief Medical Officer to the Ministry of Health, 1919-20.

weakness when the pressure fell below 100 mm., and at 90 mm., with a pulse pressure of 20 mm., he felt weak and giddy, experienced some difficulty in breathing, and could hardly stand. He was given pituitary whole gland, two grains night and morning, but this proved too much, as it caused a feeling of fullness and throbbing in the head. The amount was therefore reduced to one grain night and morning, and later on to one grain daily. While he is taking pituitary the blood pressure keeps between 110 and 122 mm. systolic with a diastolic of 78 mm. He has found, however, that if he takes it for a few days the pressure will hold up at about 108 mm. for some months without any more pituitary. Recently he suffered from influenza, his blood pressure being so affected as to be just perceptible and no more, at the radial artery. The pulse rate fell to 58. He felt so weak that he could hardly raise his head. He took one grain of pituitary whole gland and within two hours his pulse rate was 72, the artery was full and almost bounding, and he felt fit to walk.

Reviewing the above cases leaves me convinced that pituitary whole gland does act by the mouth. Not very large doses are required. Further, in certain people in whom the pituitary gland apparently needs stimulation from time to time, re-activation would appear to occur from the rest given to it by pituitary administration for a short period. In one case in which it was tried the posterior pituitary body was evidently the agent of importance. In two of the above cases Dr. Mackenzie Wallis kindly did the glucose tolerance test, which showed pituitary deficiency in both.

I bring this matter before the readers of the *Journal* believing that it will be of interest to many, and it is my intention later on, in collaboration with another, to give detailed information of the effect of orally administered pituitary whole gland on a case of low blood pressure.—I am, etc.,

London, W.1, Feb. 12th. BERNARD MYERS.

TREATMENT OF ACTINOMYCOSIS.

SIR,—The article by Dr. Hubert Chitty in the *British Medical Journal* for February 23rd (p. 347) on the treatment of actinomycosis by tincture of iodine administered in milk leads me to state briefly that during the last twenty years I have used the proprietary article called tiodine in five cases of actinomycosis, with rapid and complete success.

It is probable that iodine in any form is of great value in clearing up the lesions of this disease, but my experience, and that of many of my medical friends and colleagues, leads me to believe that the compound mentioned acts more rapidly and more effectively than ordinary iodides. Tiodine is stated by Martindale to be a chemical combination of thiosinamin and ethyl iodide, and is administered either hypodermically or in the form of pills. My attention was first called to its value some twenty years ago by the late Sir Charles Ball, who related to me the details of a case in which potassium iodide had failed to produce any effect, and in which injections of tiodine had been followed by rapid improvement. I have always employed tiodine hypodermically, and have recommended it to others in this form. In addition to my own series of five cases, I have had reports on various occasions from old students testifying to its efficacy.—I am, etc.,

T. GILLMAN MOORHEAD, M.D., F.R.C.P.I.

Dublin, Feb. 23rd.

PROGNOSIS IN ECLAMPSIA AND ALBUMINURIA OF PREGNANCY.

SIR,—Dr. Arthur Crook, in his valuable letter (February 16th, p. 320), raises some difficult points which must be cleared up before we can even begin to understand the nature of the problem we are studying. Criticizing a statement in my paper (January 19th, p. 91) he asks, "What positive evidence as yet is there available to us that kidneys were previously healthy" in the case of the initial attack of eclampsia or albuminuria in a woman with recurring toxaemia? The evidence is twofold: (1) there is ample *post-mortem* evidence in eclampsia and not inconsiderable evidence of the same kind in albuminuria that the kidney lesion is typically entirely recent and that there has been no pre-existing disease—that is, that the nephritis is secondary to the toxaemia; (2) within a few weeks of the termination of the pregnancy in a woman who recovers there is often no manifestation even to the most delicate test of any renal lesion or deficiency. In the face of such evidence dare we assume that pre-existing kidney disease has anything to do with the cause of eclampsia, etc? And why should the relationship between toxaemia and kidney be different in any subsequent attack? It would, indeed, be a strange phenomenon if in one pregnancy eclampsia or pre-eclampsia should cause nephritis whilst in the next pregnancy nephritis should cause eclampsia or pre-eclampsia! Can this mean anything save that in searching for the cause of the 50 per cent. risk of recurrence in these conditions we must address ourselves to something more fundamental than a defect in the kidney?

In the second paragraph of his letter Dr. Crook seems to urge in favour of his views the "extreme difficulty in deciding whether an albuminuria of pregnancy is a 'simple toxic' or a 'nephritic' one." The difficulty, of course, arises from the fact that, owing to a confusion of the issues, we have in the past been attempting to distinguish between things which are identical. Most of the so-called "nephritic" cases, as I showed in my paper, have really been cases of eclampsia or pre-eclampsia recurring in successive pregnancies, which are common, and not cases of primary nephritis complicating pregnancy but arising independently of pregnancy—for example, from scarlet fever—which are rare. So rare are such cases that, although we have been carefully looking for them, we have seen only two in several years. During that time we have seen many obvious cases of recurrent toxaemia. We are anxious to get records of primary nephritis in pregnancy, and I take this opportunity of saying that we would be grateful if any of your readers would kindly send to me at the Edinburgh Royal Maternity Hospital notes of any such cases under their care, stating (1) the evidence showing that the nephritis had arisen independently of a pregnancy, and (2) its effect on the pregnancies and foetus, if any.—I am, etc.,

Edinburgh, Feb. 23rd. JAMES YOUNG.

TREATMENT OF EMPYEMA.

SIR,—With regard to the treatment of empyema there is a very simple and very effective method of ensuring the expansion of the lung after operation which is not so much recognized as it ought to be, and the hopelessness of the last sentence in Dr. W. Thomas's letter on February 16th (p. 322) prompts me to draw attention to it.

The method is as follows. The patient closes the lower false cords, and by their valve-like action prevents the escape of air up the trachea. He then makes an expiratory effort, and with the outlet through the treachea closed and no counter-pressure on the one side possible (owing to the opening in the chest wall), all the force of this expiratory effort will be spent upon the collapsed lung, which will be blown up just like a football bladder.

If there is much collapse or consolidation, care must be taken not to use too much force, for fear of overstretching the more healthy parts of the lung; frequent gentle efforts are therefore desirable.

When, as not infrequently happens, the patient has no voluntary power of closing the lower false cords, it is sometimes very difficult to teach him. In such a case one can often do so by drawing his attention to the fact that the closure of this valve is an essential part of the act of straining during defaecation.—I am, etc.,

Birmingham, Feb. 18th. T. STACEY WILSON.

VITAMIN D AND THE CALCIFICATION OF BONE IN TUBERCULOSIS.

SIR,—In 1925 certain patients with bone or joint tuberculosis were given milk irradiated by ultra-violet rays, and the results then obtained appeared to justify further investigation in this direction.[1] The facts given below seem to show that this method of treatment is not as valuable as it was hoped to be.

Half a pint of milk previously exposed to ultra-violet radiations was given daily to 17 patients whose bones were partially decalcified by tuberculosis. In 7 of these patients

[1] Pattison: The Effect on Tuberculosis of Bones and Joints of Food Exposed to Ultra-violet Radiations, *British Journal of Radiology*, February, 1926.

recalcification seemed to take place more rapidly than usual; in 10 patients no such improvement was noticed.

Encouraged by the results obtained by other workers on bone calcification, irradiated ergosterol (radiostol) was given to another series of patients, an average daily dose of 2 c.cm. being used. Twenty-four children with tuberculosis of bone or joint were given irradiated ergosterol during an average period of thirty weeks. The skiagrams of 14 of these patients showed no improvement in calcification, nor could the slight clinical improvement of their local lesion be ascribed to the radiostol. In 10 cases marked improvement in calcification was noticed, but only in 5 was it more rapid than usual. As, however, these 5 patients had previously been taking cod-liver oil for several months without any change in the bone calcification, it is possible that the irradiated ergosterol is responsible for the benefit obtained.

The value of any therapeutic agent cannot be gauged adequately by the clinical examination of a series of patients, even aided by skiagrams, as except in rare instances it is impossible to obtain satisfactory controls. But it is reasonable to suppose that the administration of vitamin D will prove beneficial to patients with poorly calcified bones, and when we are able, by more exact methods, to decide the optimum dose and to select our patients more carefully, we may hope to benefit a larger number of cases.—I am, etc.,

C. LEE PATTISON, M.B.,
King Edward VII Hospital, Sheffield.

February 14th.

INOPERABLE CARCINOMA OF THE BREAST TREATED WITH RADIUM.

SIR,—In the *British Medical Journal* of February 16th (p. 319), Mr. Geoffrey Keynes refers to my article on the above subject which appeared in your issue of February 9th (p. 242).

The chief object of dividing the cases treated into "primary inoperable" and "recurrent" was to show that between 1918 and 1928 three out of every four patients presenting themselves for treatment at the Radium Institute were in the "recurrent" category. The results of treatment as regards prolongation of life show little difference in the two categories. I only considered the results of 510 cases treated from 1918 to 1925, as the remaining 123 have lived for periods of less than three years.

Primary Inoperable.—Of 125 cases (1918–25), 26 were alive at the end of three years = 20.8 per cent. Of 98 cases (1918–23), 11 were alive at the end of five years = 11.2 per cent. Of 16 cases (1918), 2 were alive at the end of ten years = 12.5 per cent.

Recurrent.—Of 385 cases (1918–25), 86 were alive at the end of three years = 22.4 per cent. Of 307 cases (1918–23), 40 were alive at the end of five years = 13 per cent. Of 66 cases (1918), 3 were alive at the end of ten years = 4.5 per cent.

I will now outline the treatment these patients received. As a routine, external applicators were applied in such fashion as to procure a "cross-fire" radiation of the breast and a general radiation of the associated lymphatic areas. A usual dose was 7,500 milligram hours; 250 mg. of radium element, screened through 2 mm. of lead, and contained in numerous applicators, were applied at an approximate distance of 1 cm. from the skin surface for six hours a day for five successive days. A second treatment was given in about six weeks, and frequently a third treatment at a further interval of two months. In many cases the treatment of a primary growth, of an ulcerated area, or of a localized recurrence was supplemented by the burying of radium needles. The needles were of high content, each containing 5, 10, or 25 mg. of radium element screened with platinum 0.3 to 0.5 mm., or 1 mm. of silver. These were left in place for periods varying from ten to thirty hours; the number of needles depended on the size of the growth.

I purposely confined my article to a review of cases treated at the Radium Institute, and followed this by some general considerations on the treatment of carcinoma of the breast. I felt sure that the details of the treatment would be of little value as these patients were treated between 1918 and 1925, since when radium therapy has made considerable progress. Since 1911 nearly 1,500 cases of inoperable breast cancer have been treated at the Radium Institute, and it is interesting to note that there is still one patient alive who was first treated in that year. She was a recurrent case who had had three operations previous to treatment.—I am, etc.,

ROY WARD,
Assistant Medical Superintendent.

The Radium Institute, London,
Feb. 22nd.

ASTHMA.

SIR,—I am much indebted to Mr. Frank Coke (*Journal*, February 9th) for referring me to his highly interesting work on asthma. I find him most appreciative of the nasal element in that disease (or symptom) as studied in the light of Dixon, Brodie, and Ransom's experiments. He uses the expression (p. 242) employed by myself in my article in the *Practitioner* in June, 1913, to the effect that a small polypus may, by intermittent contact, "tickle" (p. 11) the sensitive areas of the mucous membrane. I am therefore all the more surprised at the omission of nasal treatment in the list of methods of dealing with spasmodic asthma.

Dr. Francis, in his letter in the *Journal* of February 23rd (p. 372), recalls the discussion which took place so long ago as in 1899 in the Laryngological Society of London. He cites the views of Sir Felix Semon and Sir StClair Thomson as unfavourable to the practice of intranasal surgical treatment. My late respected friend Sir Felix Semon, in his speech at the meeting, stated that:

"cases had been noted by good observers, such as Voltolini, Bernhard Fraenkel, and others, in which the mere removal of nasal polypi, not undertaken with any view to cure co-existing asthma, had been followed by that result, *i.e.*, the asthma attacks—which had formerly been very troublesome, either entirely disappeared, or became less intense after the removal of the polypi—returned or became intensified with the recurrence of the polypi, and improved again after renewed removal. This was a very clear proof that asthma may be positively produced from the nose, and it was clearly a grave fault to altogether deny such a possibility. Nor were nasal polypi, although in the speaker's experience by far the most obvious, the only cause of nasal asthma; other forms of nasal obstruction could produce this effect, such as great tumefaction of the nasal mucous membrane, considerable deviation or excrescences from the septum, etc. In no class of cases, however, was the connexion more clearly established than in cases of nasal polypi. In the speaker's experience, relief might be given by nasal treatment in such cases—occasionally even when the asthma had been in existence for a long time, although the number of cases of the last-named category in which he had obtained satisfactory results was extremely small."

Sir StClair Thomson's reported statement in the old discussion should be read in connexion with his views as set forth in his classical textbook. In this he says (third edition, p. 209):

"The relationship between the nose and attacks of bronchial asthma is emphasized by laboratory as well as clinical experience. By the application of weak electrical currents to the nasal mucous membrane Lazarus was able to register a distinct increase in the intrabronchial pressure. Brodie and Dixon have produced spasm of the muscular walls of the smaller bronchioles by stimuli applied to the nasal septum.

"Every asthmatic patient should have his nose examined and, if necessary, treated. If polypi are present, or if there is polypoid degeneration of the ethmoid, these diseased conditions can be cleared away with good prospect of considerable, or even complete and lasting, relief in a large proportion of cases, particularly in those where the disease did not begin in childhood. Removal of adenoids should always be advised, as their presence increases the discomfort during an attack, and cure has, in some cases, followed operation. Turbinal hypertrophies should only be treated according to the usual indications, as their association with asthma is uncertain. Deviations and spurs can be left alone, unless their removal is required for other reasons."

A careful perusal of the reports of the discussion in the *Proceedings of the Laryngological Society* (vol. vi, pp. 88, etc.) will, I think, result in a modification of the impression "that the general opinion as regards the prospect of obtaining permanent relief by nasal operations was anything but hopeful."

For my own experiences I would refer to my papers in the *Practitioner* (June, 1913, and December, 1927).—I am, etc.,

JAMES DUNDAS-GRANT.

London, Feb. 26th.

CEREBRAL ANGIOSPASM.

SIR,—Dr. Gubb, in your issue dated February 9th (p. 247), and Dr. Allen, February 16th (p. 323), have both described cases of transient palsies of cerebral origin in patients over 70 under the heading of cerebral angiospasm. I feel that this diagnosis should not be allowed to stand without a query.

In the retina, obstruction of the central artery is met with most frequently in elderly patients; microscopical examination has proved that in them it is due to endarteritis with thrombosis. Here it is not uncommon to get a history of previous transient attacks of misty vision or blindness, and the general teaching in ophthalmology is to the effect that these attacks are due to a transient lowering of blood pressure in the diseased vessel, which hinders still further the trickle to the periphery and causes the temporary ischaemia.

In the cases described by Dr. Gubb and Dr. Allen possible causes for a reduction of cerebral blood pressure would appear to have been present; in the former "he was gathering figs with the head thrown back at an acute angle," in the latter "the patient rose in the morning feeling somewhat ill."

It is now generally accepted that though in arteriosclerosis with hyperpiesia the pressure is high in the arteries, it has been damped down and is below the normal in the arterioles. It would seem that an ischaemia would be more likely to result from a further diminution of pressure than from spasm of a diseased vessel wall.

A small number of cases of retinal ischaemia have been recorded in which the diagnosis of arterial spasm would seem to be justified (see *British Journal of Ophthalmology*, 1927, pp. 625-628). Temporary amaurosis from retinal spasm is mentioned in Osler's *Medicine* as having been recorded in a subject of Raynaud's disease.—I am, etc.,

London, W.1, Feb. 22nd. FRANK JULER.

PUBLIC ELEMENTARY EDUCATION.

SIR,—I am aware that when a book is sent by a publisher to a journal for review the author must be content to stand the racket of adverse criticism. However, I venture to think that your notice of my book *Mass Education in England*, in the *Journal* of February 16th (p. 311), under the title as above, misrepresents its contents. What you say might have been written "by special request" of somebody who is hit, and the book, I know, is a rude assault upon official authority, scholastic interest, and public prejudice.

Your method was to prejudice my case by complaint of the wording of a trade advertisement of the publishers, Messrs. E. J. Burrow and Co. You afterwards talk of my want of logic, but where is yours? The accuracy of Messrs. Burrow's description was, however, well borne out by an article upon the book by Mr. Horace Newte in the *Daily Mirror* of yesterday, and about a score of other journals have seen fit to handle the book with great respect and some with evident appreciation, without troubling about its advertisement. I suppose the proverb here applies as to honour in one's own country.

In vindication of myself and my book perhaps you will kindly allow me to state that the two chief points of my theme are not as you have represented them. I will restate them. They are: (1) That the effect of the compulsory entry of the greater part of the populace into those simple mechanical employments which are required to supply the daily wants of the community, as well as the daily bread of the workers, is preventive of the application and maintenance of the ordinary subjects of school learning, and of later mental culture, even where the ability of acquisition exists. (2) That the education of children to a degree beyond that which corresponds to their varying native intelligence and inherent powers of becoming educated is an impossibility. As to argument in proof of these statements, so far as No. 1 is concerned it is capable of practical test, but it can hardly be necessary to suggest to doctors that they need to make inquiries into the effect of school education and the existence of mental culture as to-day exhibited among the dwellers in working-class streets. No. 2 should be self-evident, but, if not, proof of it will be found in the statistical results of official inquiries and reports which find a careful detailed quotation in my book—one of the several facts connected with the book that you omitted to mention.—I am, etc.,

Cheltenham, Feb. 21st. J. H. GARRETT, M.D.

*** When, in connexion with a book sent for review, it is claimed by publisher or author that it contains "startling information and deductions," or that it is "a rude assault upon official authority, scholastic interest, and public prejudice," it is surely permissible to examine how far such claims are justified, and to point out, if such is the reviewer's honest opinion, that the book does not fulfil what is claimed for it. In his letter Dr. Garrett restates his two chief points. In our notice we described them in words quoted from the book itself, and they do not seem to differ essentially from the points as he now puts them.

BRITISH JOURNAL OF UROLOGY.

SIR,—It has long been a source of wonder to foreign observers that there should exist no British journal devoted to urology, which has become a universally recognized specialty, and is being taken up by an increasing number of young men in England to-day; whereas for a long time past journals of urology have appeared in America, France, Germany, Italy, and Spain. Since 1911 there has been an active British section taking part at the congresses of the International Society of Urology. Again, and when the time was ripe, the council of the Royal Society of Medicine thought fit to establish the subject of urology as a separate section, and not as a subsection of surgery, thereby showing that they held that urology was entitled to be separated off as a special subject for study.

We realize fully the generous help given hitherto by your *Journal* in publishing a number of important articles on urology as practised in Great Britain; nevertheless, we feel that there is nowadays such abundance of special work being done that can only find a voice if it can be given the additional outlet of a journal specially devoted to the subject. Such a journal is bound also to enhance the prestige of British urology. We feel sure, therefore, that our publication will in no way be hindering, but on the contrary will be supplementing, your efforts to forward the reputation of British Medicine.

A large editorial committee has been formed representing urologists in all the British-speaking countries of the world, and they intend, under our combined editorship, to bring out quarterly a *British Journal of Urology*, which will circulate not only in this country but in America and abroad.—We are, etc.,

FRANK KIDD,
H. P. WINSBURY WHITE,
London, Feb. 19th. Editors.

BANISTERIN.

SIR,—In the *Evening Standard* for February 21st there appeared a paragraph which stated, on the authority of an International News Service message, that Professors Lewin and Schuster had described to the Berlin Medical Society a new drug called "banisterin," which was considered to be "a cure against paralysis caused by organic brain diseases." A similar paragraph suggesting the use of "banisterin" in the treatment of encephalitis lethargica went the round of the Australian press in 1928.

Professor Lewin has described "banisterin" in two papers (*Archiv für experimentelle Pathologie und Pharmakologie*, April, 1928, vol. 129, p. 133, and *Comptes rendus de l'Académie des Sciences*, February, 1928, vol. 186, p. 469), and the composition and chemical characters of the alkaloid are so like those of harmine, discovered by Fritsch in 1847, as to leave little doubt in the minds of chemists that "banisterin" is harmine. Professor Lewin remarks that this has been suggested to him, but he follows his brief description of the pharmacological action of "banisterin," in the second paper mentioned above, with the remark, "To my knowledge harmine does not produce

similar effects." In the *Archiv* paper he states he is relying on published information regarding the action of harmine.

Harmine is available in England, if not in Germany, and it seems to be essential that a pharmacological comparison of "banisterin" and harmine should be instituted as soon as possible. The point is important because if Professor Lewin's results are confirmed a demand may arise for this drug, and harmine can probably be made much more easily from the usual source, the seeds of *Peganum harmala*, than from the plant utilized by Professor Lewin, *Banisteria caapi*. The latter is one of the suggested sources of the "yage" used by South American Indians as a narcotic. "Yage" has been repeatedly examined, and the two most recent papers on the subject (Elger, *Helvetica Chimica Acta*, 1928, vol. 11, p. 162, and O. Wolfes and K. Rumpf, *Archiv der Pharmazie*, 1928, vol. 266, p. 188) leave no doubt that the alkaloid it contains is harmine, though it was at first mistaken for a new alkaloid and called "*yageine*" by *Villalba*. Moreover, Wolfes and Rumpf state that Professor Lewin obtained his alkaloid from the same plant material as they did. The remarkable properties ascribed to "yage" are reflected in the name "telepathine," which Bayon gave to an alkaloid he obtained from "yage," and which is probably also harmine.—We are, etc.,

London, E.C.1, Feb. 25th. BURROUGHS WELLCOME AND CO.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

IN the House of Lords, on February 26th, the second reading of the Local Government Bill was moved by the LORD CHANCELLOR. Lord PARMOOR moved the rejection of the bill, and the debate was adjourned.

The committee stage of the Local Government (Scotland) Bill was completed in the House of Commons on February 25th.

On February 20th Colonel GRETTON presented a Hospitals (Relief from Rating) Bill "to grant complete or partial relief from rates in the case of certain hereditaments used for the purpose of hospitals, infirmaries, dispensaries, convalescent homes, sanatoriums, and other similar uses, or in connexion therewith."

Dr. Fremantle presided, on February 26th, over a well-attended meeting of the Parliamentary Medical Committee. The Committee considered a communication from the Asthma Research Council concerning a complaint received from a practitioner who alleged that his treatment of asthma had not been duly investigated. The Committee received a deputation from the Medical Practitioners' Union. Speaking for the deputation, Dr. GORDON WARD complained of the limitations on the prescriptions of panel practitioners. His union considered that the provision of drugs should be a separate benefit, but he admitted that there should be restrictions, and suggested modifications of the present procedure. Reference was made to the London list of prohibited drugs, which had been drawn up by the Insurance Committee and passed by the Panel Committee. The Parliamentary Medical Committee undertook to consider the question.

Local Government (Scotland) Bill.

On February 20th the House of Commons was again in committee on the Local Government (Scotland) Bill. Clause 25 provided against failure of the town councils of small burghs with respect to water supply and public health obligations. Dr. ELLIOT, for the Government, moved to modify the clause to enact that where the local authority of any area had failed to discharge its functions with respect to the provision of water supply, or of sewers or drains, or with respect to housing, or had failed to discharge any other functions relating to public health, the department might authorize any other local authority to discharge the functions of the defaulting authority. In moving the clause Dr. Elliot said the Secretary of State for Scotland was precluded from doing so by influenza. Dr. DRUMMOND SHIELS agreed that these powers should only be put into operation after inquiry. By 196 to 86 the clause was amended as proposed by Dr. Elliot.

Clause 26 authorizes the county medical officer of health and sanitary inspector to act for small burghs. Mr. W. ADAMSON moved to leave out "or sanitary inspector." He declared that otherwise these burghs might be deprived of the services of whole-time sanitary inspectors. Sir ROBERT HORNE concurred.

Dr. ELLIOT said that of 179 small burghs in Scotland 26 had appointed the county sanitary officer to look after them, 106 had full-time officers, and 47 had part-time officers. The appointment was becoming more technical and skilled. The Scottish Board of Health had done its utmost to raise the status of the sanitary officer and to make clear that his position was in some ways more important than that of the medical officer of health. A whole-time sanitary officer could not be removed without the consent of the Board of Health, but they had known cases where pressure had been exerted on part-time officers. It was not suggested that a man would have to cover a whole county such as Lanark or Fife. He would work with assistants.

Mr. T. JOHNSTON denied that the administration of public health was inefficient in the small burghs. These burghs had a lower infantile death rate and lower death rates for ages under 25. When the burghs inspected milk and dairies, cows were inspected at least four times a year. Now, under the county councils, the inspection was at most twice a year, and in other parts once a year.

Dr. SHIELS remarked that the supporters of the amendment had not challenged the proposal to centralize under the county medical officers, although many burghs in Scotland would be reluctant to depart from having their own medical officers. He agreed that in some of the smaller burghs the work of the sanitary inspector could be better done by the county officer, but it was ridiculous to say that a burgh like Musselburgh, with a population of 17,500, had not sufficient work to occupy a full-time sanitary officer.

The LORD ADVOCATE (Mr. W. Watson) said the Government would accept the amendment provided it remained free to reinsert the words during the report stage or to make variations.

The House then agreed to the amendment not to make county sanitary inspectors the sanitary inspectors for small burghs.

Sir ROBERT HAMILTON then moved an amendment designed to leave the burghs freedom of choice in the appointment both of medical officer and of sanitary inspector. Under the clause as in the bill, the county medical officer or county sanitary officer would, in the event of a vacancy in the similar post in a burgh, be automatically appointed for the burgh unless the Board of Health agreed otherwise. Sir Robert thought that the town council of the burgh should be left to say if it desired that the county medical officer should be appointed medical officer of the burgh.

Dr. ELLIOT said the case for the appointment of the county medical officer to the smaller burghs was stronger than that for the appointment of the county sanitary officer; such appointments had been made by 100 out of 179 burghs affected. The medical officer had to deal with larger functions of health, which to a considerable extent were being transferred to the reconstituted county authority.

Dr. SHIELS could not support the amendment. The burghs which objected to appointing the county medical officer might not be the most suitable ones to have medical officers of their own. The medical officer of health of the smaller burghs had been a local figure of importance, and had in many cases done magnificent work, but with the advance of medical science, laboratory and scientific equipment, such as the small unit was unable to furnish, was needed to deal properly with public health. He agreed that places such as Rothesay, Oban, St. Andrews, and Dunoon, which had large summer populations, ought to have their own medical officers of health, and the Board of Health in Scotland would take advantage of the reservation in the clause permitting this. In medical matters the department of the Board of Health had always been up to date and progressive.

Dr. ELLIOT said the Board would take advantage of the provisions to deal with exceptional cases such as arose at sea-side resorts. There were cases of small authorities appointing unsuitable men. A local authority in 1919 appointed a medical officer of health who did not possess the statutory qualifications, and the Board had to negotiate over the matter till 1928.

Sir Robert Hamilton's amendment was defeated by 233 to 43, and after minor amendments had been made the clause was added to the bill.

On February 21st Mr. ERNEST BROWN moved an amendment designed to leave out of the block grant the health grants. He said no issue in the bill caused more disquiet in the country than the change of grants for health services from the percentage to the the block system. The amendment proposed to leave out from the operation of the block system the maternity and child welfare grant for Scotland, amounting to £157,000; the grant for tuberculosis treatment, amounting to £347,000; the grant for venereal disease treatment, amounting to £66,000; the grant for the welfare of the blind, £20,000; and the mental deficiency grant, £16,000—in all, £667,000. The block grant system would set up a competition among idealists in which one would want more money for tuberculosis treatment, another more for maternity and child welfare, and another more for the treatment of venereal disease.

Dr. ELLIOT said this was one of the major issues of the bill, and would confront Governments for many years to come. The percentage grants had worked unsatisfactorily in some cases. Large areas had no child welfare schemes at all. Under the bill the Highland counties would receive over £60,000 a year, and the Government would have power to call for the institution of such

services. The Government scheme provided cash and compulsion. Previously the local authorities had developed health services under the Poor Law in Glasgow, Aberdeen, and many of the burghs and counties of Scotland, although those services did not attract one penny of grant. The payment or withholding of a grant had not affected the hospital treatment of measles in Glasgow.

Mr. WILLIAM GRAHAM said that before the Meston Committee the Scottish Board of Health had given evidence supporting the percentage grant system as applied to public health services.

Mr. JAMES STUART said the Board of Health had coaxed Glasgow to increase the hospital treatment of measles and whooping-cough, and gave a grant of £20,000. To-day the average annual expenditure of Glasgow for the treatment of measles and whooping-cough was £21,000, but instead of getting £10,500, which was promised by the Government, the city was now only to receive £4,500. Last year Glasgow spent £116,000 on child welfare, and of that sum received £53,000 from the Government. Glasgow contemplated a development of its child welfare service and the provision of more maternity hospital accommodation, but under the bill it might not get any advantage under the block grant in respect of such developments. Glasgow was spending £220,000 annually on the treatment of tuberculosis, and hoped to open a new hospital this year costing in round figures £400,000, with 440 beds. All the charges for interest and sinking fund would have to be added to the maintenance of cases, and the cost per patient per week, including treatment and administration, would run from 55s. to 60s.

Dr. DRUMMOND SHIELS said no medical authority would have pleaded for a change from the percentage to the block grant system. Public health services were developing fast, and had in many cases doubled or trebled in amount since they were instituted. He hoped that even if all other services came under the block grant system an exception would be made for child welfare and maternity. Ante-natal supervision lessened the maternal death rate, and an adequate ante-natal service in every centre of population was essential. In Edinburgh, Glasgow, and other cities they had a fairly good service, but even in these places the number of centres was insufficient, while the accommodation and comfort were far from what they should be. Edinburgh contemplated a scheme for debilitated children which was to cost £25,000. Whether it would go on was now uncertain, as the past year had been the standard year under the bill, and any expenditure over the amount of that year would for the next three years fall on the ratepayers. The treatment of venereal disease was specially endangered under the block grant. It was an unpopular service, which previously got 75 per cent. from the State. Henceforth the local authorities would have to find 100 per cent., and the service would suffer, especially if the Government carried out its suggestion of dropping all assistance to propaganda. The blind rightly feared that under the new arrangement they would have cursory treatment from some of the local authorities. In the mental deficiency service a great advance was needed, and any grant based on the standard year would be inadequate. There was no place in Scotland where the health services were completely adequate to the needs of the community. Outside Glasgow, Poor Law institutions on the health side were by no means well equipped.

Dr. ELLIOT said the proposed grant was not a stereotyped block grant, but one with frequent periods of revision. Its operation could be watched and any errors corrected. If expenditure was good and commended itself to local authorities they would undertake it even if not immediately sure of recoupment by the central authority. If the local authorities so undertook expanding services the Exchequer contribution would recognize that in its successive revisions. The scheme provided a flexibility which had not hitherto existed in relations between the local authority and the central authority.

Mr. Brown's amendment was defeated by 174 to 102. An amendment by Dr. Shiels to except the percentage grants for maternity and child welfare was defeated without debate by 181 to 106. An amendment by Sir Robert Hamilton to except a grant to Highland counties was withdrawn after Dr. Elliot had explained that the Highlands and Islands medical grant had not been swept away, but would have to be substantially increased.

On February 22nd the House discussed Clause 48, which provides for contributions to voluntary associations in respect of the welfare of the blind and of mental defectives. Dr. DRUMMOND SHIELS moved to add a subsection providing that the central department might, before the beginning of each fixed grant period, make a scheme providing for the payment by county councils and town councils of large boroughs of specified amounts to an approved organization providing general publicity and educative propaganda in furtherance of the prevention and treatment of venereal disease. He said the proposal of the Government, as implied in the omissions from the bill, to drop the grants which had been previously made was unwise. His amendment had the approval of members in all parties. Last year the House had rejected the bill in which the Edinburgh Corporation sought power to compel those who suffered from venereal disease to undergo treatment. The House then decided, under the guidance of the Minister of Health, that the voluntary system was sufficient. Dr. Shiels held that a purely voluntary system would not stamp out these diseases, but it could not succeed unless the public understood and realized the seriousness of these conditions. A similar amendment to that he now moved had been put forward to the English Local Government Bill, and the Minister of Health could not accept it. In the present amendment, however, the word "may" had been substituted for the word "shall." A committee of the British Social Hygiene Council had carried on this propaganda in Scotland since 1921, giving lectures, advertising, and distributing literature, particularly in areas where cases were not coming to the clinics. The Scottish Board of Health had given £1,000 a year towards the work, and the report of the Board for 1927 declared that the work of the Scottish committee had been effective and of high value. Those who were in charge of the treatment of these diseases in Scotland were convinced that if things were left as in the bill the local authorities would not voluntarily contribute to the funds of such an association.

Dr. ELLIOT said propaganda with regard to venereal disease was of vital importance and in many ways better exercised from a central body than from a local body. There were conclusive difficulties against compelling local authorities to contribute to voluntary associations. Under the bill the small grants which had been made from time to time to this or that organization were being swept into a general pool, and that pool would be assigned to local authorities, who, he hoped, would then take upon themselves all and more than all the duties which the central department had previously stimulated them to carry out. Local authorities should feel full responsibility for all health activities in their area, including responsibility for propaganda. He proposed that the present grant from the central authority to the voluntary society should be continued up to May, 1930, and that a substantial additional sum be obtained from the Treasury towards the expenses of that society. He would also call a meeting of the local authorities who were particularly concerned in the matter and discuss the subject with them. He had no doubt they would agree on the health and propaganda work which they desired to carry on. The Government would act as banker for any sums which the local authorities might wish to spend on health propaganda, including that against venereal disease. The local authorities would themselves contribute freely and not under the compulsion of the central department. It might be that in future local authorities would wish to undertake this work themselves, but the position of the society would be safeguarded for a year. The danger that local authorities might not act was guarded against by Clause 50, which provided that the Secretary of State should be satisfied that a council had so carried out its obligations that the health of the inhabitants was unlikely to be endangered. The Department of Health in Scotland had no special appropriation for health propaganda or for preventive publicity work. Propaganda against venereal disease was clearly one of the health duties of local authorities. Care of mental defectives and of the blind was more welfare work than health work.

Mr. JAMES STEWART asked the Government to take power to deal with any local authority which was not continuing the propaganda against venereal disease. Some very considerable local authorities showed no enthusiasm in dealing with the disease.

Mr. ROSSLYN MITCHELL compared the growth of the campaign against venereal disease and the arousing of public interest to the steps taken to eliminate ophthalmia neonatorum in Glasgow. That disease had brought to Glasgow from 150 to 200 blind children every year, but in fifteen months from the introduction of compulsory notification and of public treatment there was no case, even of the loss of one eye.

Dr. SHIELS was glad to hear what Dr. Elliot offered to do, but could not regard it as a satisfactory substitute for the amendment. If Dr. Elliot would reconsider the matter before the report stage, Dr. Shiels would withdraw the amendment.

Dr. ELLIOT promised to bring the debate to the notice of Sir John Gilmour. Health propaganda should not be considered merely in relation to venereal disease, but on a somewhat wider ambit. The Government could not guarantee or suggest that the funds should be spent through certain organizations. Some entirely different method might be found.

Dr. SHIELS then asked leave to withdraw his amendment, and the House granted permission.

Clause 50, giving the Secretary of State power to reduce grants for inefficiency, was amended by adding maternity and child welfare, lunacy and mental deficiency, and the welfare of the blind as services in which efficiency could be demanded. The Lord Advocate desired to make clear that the clause applied to welfare services as well as to health services.

On February 25th Mr. MACROBERT, Solicitor-General for Scotland, moved a new clause to enable local authorities to submit schemes for reorganization with a view to removing the distinctions between Poor Law patients and the public health patients, and to provide for hospital treatment under the public health authorities and not under the Poor Law. He said that in the clause there were safeguards with regard to the voluntary hospitals, and one of the objects of the clause was to secure co-operation between the public authorities, the voluntary hospitals, and the medical schools. The schemes for reorganization had to be submitted to the

Secretary of State for Scotland by the various authorities, either county council or borough council. A wider definition was given of the words "hospital facilities." Power was given to the authorities to spend money in extensions where the present facilities were inadequate. The department would satisfy itself with regard to an appropriate scheme by inquiry, not necessarily by a formal or local inquiry. In the event of a scheme not being approved on terms by the department they might modify or amend it. Statutory powers were given to the authorities in connexion with general hospital services. At present they only had statutory powers in regard to hospitals for infectious diseases. The powers were to be extended to general hospitals. Authorities were granted power to give hospital services for people living in another area.

Mr. STEWART urged that it should be made obligatory on every county council and town council to prepare a scheme for the consideration of the central department.

Lieut.-Colonel MOORE said he represented some of the most progressive seaside towns in Scotland. In the arrangements made for a very large summer population hospital accommodation was very prominent. In certain cases the town councils had established very fine hospitals for fever and other cases, and out of the rates they had practically paid off the entire capital cost incurred in building and equipping the hospitals. Under this new clause these hospitals would be taken over by the new county authorities, and as far as he could see no question of compensation arose.

The CHAIRMAN pointed out that Colonel Moore could not raise that question at that point as it came under Clause 6.

Lieut.-Colonel MOORE said that in that case he would ask the Government to bear in mind that there was a feeling that these towns should be compensated for the capital expenditure which they had incurred in respect of these hospitals.

Dr. SHIELS said that the Labour party agreed with the main principles of the clause, but there were certain features which they would like to see altered. In the larger industrial districts in Scotland and England hospital arrangements were in a more or less chaotic condition. Reorganization in these cases was absolutely essential if the full facilities available in the public and voluntary hospitals were to be utilized. If the clause was to be permissive they would still be left in the same old position with regard to reactionary or lazy authorities. One of the hopeful features of the section dealing with the extension of hospital facilities was that it provided some remedy for the serious condition of the voluntary hospitals as regarded their accommodation. The Mackenzie Commission, which reported in December, 1925, gave the total number of voluntary hospital beds in Scotland as 8,589. There had probably been an increase since that time, but they estimated that 3,600 additional beds were immediately needed in order to provide the necessary accommodation. The Edinburgh Royal Infirmary had a waiting list of over 2,000 people, many of them being cancer cases. The same was true in regard to Glasgow, and indeed the voluntary hospitals of Scotland did not provide except very partially for the needs of the community. In the Poor Law hospitals and sick wards of poorhouses there were 6,100 beds. Of that number 4,285 were grouped in the larger Poor Law hospitals. One effect of this new clause would be that in those cases where the Poor Law beds were not fully occupied they would be available to the local authority to meet the needs of the sick people in the district. It was surely even more necessary that immediate steps should be taken, seeing that there were these facilities, to prepare a scheme, not only for co-ordination, but for making the necessary additions and extensions in areas which quite evidently required it. In regard to the inquiry mentioned by the Solicitor-General, he wished to know whether it was a public inquiry with witnesses, whether it was likely to be expensive, with counsel representing the various conflicting authorities, and whether people with vested interests would be able to object to the necessary extensions and either defeat the object of the local authority or add considerably to its expenses in establishing approval of the proposed scheme.

After further debate the LORD ADVOCATE said that the Government felt that it would be a bit hard and unwise to make the preparation of schemes mandatory in the way which had been suggested. But he would point out that under Clause 50 every local authority was bound to exercise its functions up to a certain standard and to provide adequately for the health of the people in the district. The word "function" was defined as including not only duties but powers, and as a lawyer he said that the power which was conferred on local authorities in this clause was one which they would be bound to exercise, otherwise their grant would be reduced.

The clause was read a second time and added to the bill.

The LORD ADVOCATE moved a new clause dealing with the recovery of expenses in connexion with the treatment of the sick. He said that at present the Poor Law authority had power to recover expenses for the treatment of poor persons from those who were legally liable for the maintenance of those persons, and it was now proposed that all the hospitals under the new sick persons scheme should be put more or less on the same basis. The Poor Law power, of course, would remain with the new body. There was an exception in the case of infectious disease, and the reason for that was obvious. According to the customary practice patients were compulsorily removed for the benefit of the community at large, and that made all the difference. The amount to be recovered was limited to a reasonable amount.

Dr. SHIELS said that he was glad that the Government had now amended this clause in accordance with suggestions made by the Opposition, and to that extent he thought it was a great improvement on the original drafting. The use of the word "reasonable" was a great improvement. But they protested against the distinction still drawn between infectious and other diseases. He would like to say something about the maternity hospitals. A great deal was being done in regard to the reduction of maternity mortality, and one proposal which seemed likely to be fruitful was that, instead of one big maternity hospital, there should be a number of smaller hospitals in different parts of the town or the county where patients could be more readily and quickly attended and where a certain amount of isolation could be secured in cases where there was an infective condition. There was great scope for this development, because they knew that diseases associated with these conditions were responsible not only for many deaths, but for a great deal of chronic ill health. They wanted to encourage the most ample provision for maternity hospitals. Yet in spite of the optional nature of this clause, and in spite of the insertion of the word "reasonable," it was still possible under it that a maternity hospital would have charges so high that women who required the treatment very badly would not be able to take advantage of its facilities. Therefore he urged the Lord Advocate very strongly to concede the exemption of maternity hospitals from the general operation of the clause.

After further debate the clause was read a second time and added to the bill.

An amendment moved by Dr. SHIELS to exempt maternity homes from the clause was rejected by 203 votes to 88.

The committee stage was completed, and the bill as amended was reported to the House.

Assessment of Voluntary Hospitals.

In an answer to Mr. Robert Morrison, on February 20th, Sir KINGSLEY WOOD said the Rating and Valuation Act had not altered the basis of the valuation of hospitals. It was open to assessment authorities now, as heretofore, to adopt a basis which would take full account of the special circumstances of voluntary hospitals dependent on contributions from the public and of the responsibilities, conditions, and restrictions which affected their rateable value. Full rights of objection and appeal were available to any governing authority which was not satisfied that due regard had been paid to these factors and was aggrieved by the assessment proposed. Sir Kingsley repeated the declaration previously made that the de-rating of hospitals could not be considered apart from the de-rating of other charitable institutions, and that legislation to that end could not be introduced in the present Parliament. He added that the British Hospitals Association, at Mr. Chamberlain's suggestion, proposed to submit to the Central Valuation Committee proposals for greater uniformity in the assessment of voluntary hospitals and the adoption of a generally acceptable basis of valuation. This suggestion had been adopted after an interview between the Minister of Health and the representatives of British hospitals.

Dr. VERNON DAVIES asked whether the Parliamentary Secretary was prepared to support the proposals of the British Hospitals Association when these came before the Central Valuation Committee.

Sir KINGSLEY WOOD replied that the Ministry would do all it could to assist, but had no statutory authority to interfere with the policy of the Central Valuation Committee. That committee had made certain suggestions which would promote uniformity and might lead to good results.

Report on Mental Deficiency.—Lord EUSTACE PERCY announced, in an answer to Mr. Robert Morrison on February 21st, that he was arranging for the publication of the first section of the report of the Departmental Committee on Mental Deficiency. This report would include all the committee's findings and recommendations on matters falling within the scope of the Board of Education and of the local authorities, together with the report of a survey of the incidence of mental deficiency in certain typical areas, carried out by one of the medical officers of the Board of Control. Lord Eustace Percy feared these documents would not be available before Easter. He thanked the committee for its valuable report which would greatly assist all interested in the education of mentally deficient children.

Invaliding for Tuberculosis.—Colonel HEADLAM, on February 6th, stated that since the new rules relating to the assessment of attributability of tuberculosis came into operation in the Navy on October 1st last, 70 cases of invaliding for tuberculosis had been considered. In 46 cases disability pensions had been granted, and 10 cases were under consideration. Ten cases dealt with before October 1st had been reconsidered, and, in the absence of fresh medical evidence, the original awards had been maintained. Dr. Shiels was informed, on February 21st, that the Secretary for Scotland could not give the number of tuberculous ex-service men in Scotland apart from those on the registers of the Ministry of Pensions.

Obituary.

G. NEWTON PITT, M.D., F.R.C.P.,

Consulting Physician to Guy's Hospital.

WE much regret to announce the death, on February 22nd, at Walton-on-Thames, after a short illness, of Dr. G. Newton Pitt, for many years physician to Guy's Hospital, and for the past fifteen years intimately associated with the work of the Royal Medical Benevolent Fund.

George Newton Pitt was born in London on October 15th, 1853, the eldest son of George Pitt of Sutton, Surrey. From Christ's College, Finchley, he went to Clare College, Cambridge, with a scholarship, and was placed tenth wrangler in the Mathematical Tripos of 1876. In 1879 he was elected a Fellow of Clare College, and during the tenure of his Fellowship studied medicine at Cambridge and at Guy's, qualifying as M.R.C.S. in 1881. In 1884 he graduated M.D., B.Ch.Cantab., and obtained the M.R.C.P. Lond. diploma. In 1890, the year after his election as a Fellow of the Royal College of Physicians, Dr. Pitt was appointed Goulstonian lecturer. In 1903–7 he served as examiner to the College, was a member of the Council in 1907–9, *Bradshaw lecturer in* 1910, censor in 1914–15, and senior censor in 1918. His Goulstonian Lectures on "Some cerebral lesions" were published in the first volume of the *British Medical Journal* for 1890, and his Bradshaw Lectures on "The results of bronchial obstruction" appeared, with illustrations, in our issue of December 10th, 1910. From 1887 onwards Dr. Newton Pitt was a member of the staff of Guy's Hospital, serving in turn as demonstrator in morbid anatomy, assistant physician, physician and lecturer in medicine, and, finally, as consulting physician. In the early part of his career he was also assistant physician to the East London Hospital for Children at Shadwell, and was for some time an examiner in medicine to the Universities of Cambridge and London. For his war services as major, attached to the 2nd London Territorial General Hospital, he received the O.B.E.

DR. NEWTON PITT.

Dr. Newton Pitt was for many years a member of the British Medical Association; he held office as vice-president of the Section of Pathology at the Annual Meeting of the Association at Manchester in 1902, and as vice-president of the Section of Medicine when the Association held its Annual Meeting at Exeter in 1907. Besides his Goulstonian and Bradshaw Lectures, and contributions to Allbutt's *System of Medicine* and Allchin's *Manual of Medicine*, he was the author of a number of papers in *Guy's Hospital Reports*, and between 1901 and 1908 contributed eight articles to the *British Medical Journal*, mainly on diseases of the heart and of the central nervous system. His presidential oration before the Hunterian Society was entitled "John Hunter as a physician and his relation to the medical societies of the last century." To his invaluable work for the Royal Medical Benevolent Fund, from the time of his appointment as honorary secretary in 1914, a tribute is paid by his former colleagues in the appreciations printed below.

His active years at Guy's were marked by unremitting attention to the patients under his care, and to his duties as a teacher of clinical medicine. His intimate knowledge of morbid anatomy, gained as a demonstrator in this subject over several years, illuminated the bedside teaching, and gave an authority to his instruction of the highest order, while his constant attendance at operations which he had advised gave him a knowledge of living pathology and that form of information so essential to a physician dealing with acute abdominal conditions. His clear logical mind enabled him in his teaching to sift the material, to free it from ambiguities, and present the subject in hand in a manner to be grasped by the student. The teaching was illustrated from a wide and well-garnered experience, was never diffuse, and the essentials were impressed as by the hand of a master. These same qualities were of signal service in the management of the medical school, and on the various committees co-ordinating the relation between the hospital and the school, where his opinion, always given after mature reflection based upon a knowledge of the subject which he had been at pains to acquire, carried great weight.

Sir CHARTERS SYMONDS, consulting surgeon to Guy's Hospital and honorary treasurer of the Royal Medical Benevolent Fund, writes:

As a colleague Dr. Newton Pitt gained the esteem and affection of all the members of the staff, and was beloved by the students, many of whom became his intimate friends. For many years he was consulting physician to the London Orphan School, where his services were frequently called upon. The Royal Medical Benevolent Fund has lost in Dr. Newton Pitt an honorary secretary who for fifteen years gave devoted service to the relief of numbers of the profession and their dependants. It was his special part to investigate all applications, by examination of statements, and often by personal interviews. Over this he spared no trouble, and when the application was placed before the committee his award was almost invariably accepted. Before the present secretary was appointed and the present offices were established the duties demanded daily supervision, a special corner of his study being set apart for the purpose. He had an intimate knowledge of both annuitants and grantees, and, while always sympathetic, was careful to see that charity was wisely distributed, and that overlapping of other bodies was safeguarded. His financial abilities were of no mean order, and his knowledge of accounts always of value. It will be difficult to find another with so original a mind, of so wide an experience, with such a knowledge of the needs of the profession, and one who is able and willing to sacrifice so much of his leisure to fill his place. No one seeing his clear mental grasp of a problem, his untiring energy, his deep interest in the affairs of the Fund, as exhibited at the meeting in the week preceding his death, could but anticipate many years of active work. It is not improbable that the severe attack of influenzal pneumonia last year seriously weakened his powers of resistance.

Dr. JOHN FAWCETT, consulting physician to Guy's Hospital, writes:

Dr. Newton Pitt was one of the three physicians appointed on the staff of Guy's in 1887 to fill the vacancies resulting from the rapid promotion among the junior members which ensued, in the main, as a sequence of the

appalling series of disasters which befel the medical staff from the year 1883 to 1887; I mean the deaths of those famous physicians, Fagge, Moxon, Mahomed, and Carrington. Dr. Leonard Wooldridge and Dr. Cooper Perry, as he then was, were the other two physicians appointed at the same time, and before two years were out Guy's had lost that brilliant genius Wooldridge, to be followed but a few years later by the deaths of Dr. Washbourn and Dr. J. H. Bryant. Dr. Pitt came to Guy's with a great reputation from Cambridge, where he had taken high rank as a wrangler, and later was elected a Fellow of his College, Clare. Throughout his period of service on the active staff of Guy's, which ended in 1913, he entered heart and soul into all the activities of both the hospital and its school.

Perhaps the features which we, as students, remember best were, first, his superabundant energy, the almost meticulous thoroughness with which he investigated the cases under his care, especially those in relation to the central nervous system, in which he was particularly interested, and where he did such good pioneer work. His brain to us seemed teeming with so many facts, with time as the sole brake to the expression of what he could do and say, and where we learned, meanwhile, of many things of which we had not even dreamt before. Fatigue was altogether foreign to his mind and nature, although by no means so to the somewhat exhausted members of his "firm," male and female, who followed in his train, at the end of a long round. Some years later, when no longer a student, I ventured to ask him if he was ever tired, and he replied, "I don't remember it," and I believe he spoke the truth. But some few days ago I met him in the "Tube" on his way to the Alliance Assurance Company, where he had been one of the medical officers for a great number of years, and he looked as well, almost as young, and spoke as robustly as ever. The only complaint he had to make was that someone had advised him recently to have all, or most of his teeth extracted, with the result that he had been uncomfortable ever since, and that was all he had to say in reference to the present state of his health. It seems impossible to realize that he is gone, and that we, and all who knew him so well at Guy's and elsewhere, have lost a very dear friend.

The other chief characteristics to my mind, and, indeed, to that of others also, were his geniality, his good humour, his love for his fellow man, particularly if he came from Guy's, and his wish to do something for him if he could. He was such a gentleman. As students we always spoke of him as "dear old Pitt"; irreverent it was, but the phrase seems to enshrine his memory, and to describe with truth the affectionate regard in which he was held by all the students, by his own house-physicians, and by his colleagues on the staff—and what can man want more! When the war came, though over 60 years of age, Pitt worked devotedly from first to last at the 2nd London General Hospital, where he held the rank of major; and also, if I recollect aright, he acted as physician at another war hospital, King George's, as it was called.

Outside Guy's the work for which he will, and should, ever be remembered is that which he did for the Royal Medical Benevolent Fund. Sir Charters Symonds recalls in the *Times* of to-day (February 26th) how that Pitt became secretary of the Fund in 1914, and that to Pitt fell a large part of the additional work entailed in the collection, the management, and the distribution of the £20,000 collected from the medical profession, with the added £10,000 from the National Relief Fund. The money was to assist financially the medical officers, especially of the Territorial Army, who had suffered loss either themselves, or, it might be, their families, from whom the breadwinner had been taken or who had died. Ever since Pitt became secretary the interests of the Fund were his constant care, and, while anxious to see it develop on a wider and more broadly comprehensive basis, yet he never failed to devote daily consideration to the numerous cases which came for relief. To those who might wish to do something to perpetuate their affection for Dr. Pitt I can imagine nothing which would have more appealed to him than an attempt to render this Fund even more generally recognized in our profession than it is at present, to have it regarded as a liability which every medical man should incur by becoming an annual subscriber. Dr. Pitt was ever grateful for the support accorded to the Fund, increasingly so of recent years, by the members of the British Medical Association.

This brief sketch, written at such short notice, does but meagrely fulfil its aim; but it may perchance serve in part, though inadequately, to express the feelings and thoughts of some who knew Pitt well, and who realize to the full how rich was his life for others, and therefore so happy for himself. He loved his life and his work, and, sad as we are to lose him, yet we recognize that, not only did he play the game hard throughout his long life, but that he put many a good innings to the credit of his side.

[The photograph of Dr. Newton Pitt is by Elliott and Fry, Ltd., London.]

DENIS WALSHE, M.D.,

Past-President, South-Eastern of Ireland Branch, British Medical Association.

WE regret to record the death, at the age of 85, of Dr. Denis Walshe, which took place at his home in county Kilkenny on February 21st. Dr. Walshe received his medical education at the Catholic University, Dublin, and at Edinburgh. In 1869 he obtained the L.R.C.P. and L.R.C.S.Ed. diplomas, and in 1871 the L.R.C.P.I. and L.M. In 1915 the National University of Ireland conferred on him the degree of M.D. (*honoris causa*).

After qualifying Denis Walshe spent several years in England holding appointments as resident medical officer at the Chorlton Hospital, Manchester, and later at the Poplar and Stepney Sick Asylum, London. On returning to Ireland he was appointed to the Tiscoffin Dispensary district, and proceeded to build up an extensive private practice. In 1883 he became medical officer to the [illegible] Dispensary District, and in 1903 coroner [illegible], both of which offices he held until his death. Dr. Walshe was an active and loyal member of the British Medical Association. He was a member of Council nearly continuously from 1900 to the day of his death, and a member of the Irish Committee since 1923. In 1900 he was a member of the South-Eastern of Ireland Branch Council, becoming its president in 1901. He represented the Kilkenny Division of the South-Eastern of Ireland Branch Council in 1916, and the Carlow and Kilkenny Division during the period 1917-29. From 1916 he was a member of the South-Eastern of Ireland Branch Ethical Committee, and since the passing of the Insurance Act he was chairman of the local committee. For nearly sixty years he never missed an Annual Meeting of the British Medical Association; indeed, although his health was so poor last year that he was urged by his medical friends not to undertake the long journey, he attended the Annual Meeting at Cardiff. A few days before his death he received a letter from Dr. Alfred Cox, the Medical Secretary, which he greatly appreciated, and showed with pride to his medical friends when they called to see him, and the Council at its last meeting also asked the Chairman of Council to send its wishes for his recovery and its appreciation of all his good work for the Association. Denis Walshe was a genial and companionable friend and the soul of hospitality. His funeral was attended by a large number of medical colleagues and friends, including Dr. T. Hennessy (Irish Medical Secretary), who travelled from Dublin to be present.

Dr. ALFRED COX writes: The Association has had many loyal and devoted members in Ireland, but none in my time whose personality was so distinctively associated with the lovable and humorous qualities one is inclined to think of as being peculiarly Irish. I never realized what a power he was for good until I met Dr. Walshe on his own ground in his own Branch two years ago. I then saw what a great factor he had been in preventing among the medical profession the growth of any semblance of a division between North and South. During times of great stress and difficulty he kept the B.M.A. flag flying [and thereby] preserved the union of the Irish medical profession, being backed in this by others in both South and North. For this alone he deserves our gratitude and remembrance. But many of us will miss even more the loss of that exceedingly

charming personality without which the Annual Meeting will seem something different and less attractive. He was for many years a member of our Council, and rarely said a word, but there were few more popular or more deservedly respected members of it.

The death occurred on February 20th, at his residence, Old Castle Gate, Banff, of Dr. WILLIAM FERGUSSON, a well-known practitioner in the North of Scotland. Born in 1855, he was a son of the Rev. William Fergusson, Free Church minister at Ellon, and went through the medical course of Aberdeen University. He graduated M.B., C.M. with highest honours in 1877, proceeding M.D. in 1879. His first four years of professional life were spent in practice at Fraserburgh, but he went to Banff in 1880, where he spent forty-nine years, gaining a great reputation both in family practice and as a consulting physician, for which his services were in request over a large area in the North of Scotland. Dr. Fergusson held various official positions, being consulting surgeon to Chalmers's Hospital, surgeon to Banff Prison, parochial medical officer for Boyndie and Alvah, and Admiralty surgeon and agent in Banff. He was associated for a long time with the local Volunteer Force, and held the position of surgeon colonel to the 1st Banff R.G.A. Volunteers, in which his long period of service was recognized by the Volunteer Decoration. He was an active member of the British Medical Association, and had attained the position of president in the Northern Counties of Scotland Branch and in the Aberdeen Branch of the Association. He was also a justice of the peace for Banffshire. From time to time he contributed articles to various medical journals, chiefly upon subjects in the department of gynaecology. Four years ago he retired from private practice, but still maintained his connexion with Banffshire Asylum, where he continued to act as visiting physician. He is survived by a widow and one son.

Dr. J. LOGAN STEWART, consultant tuberculosis officer to the Lancashire County Council, died in Manchester from pneumonia on February 20th, at the age of 49. Dr. Stewart received his medical education in Glasgow, graduating M.B., Ch.B. in 1905; he obtained the diploma D.P.H.Camb. in 1908. He entered the service of the Lancashire County Council as medical inspector of schools in 1909, and in July, 1913, he was appointed consultant tuberculosis officer for the south-east portion of the county, at present containing a population of 370,000 persons, with a chief dispensary at Ashton-under-Lyne and five branch dispensaries in neighbouring towns. Dr. Stewart was the first member of the tuberculosis medical staff of the Lancashire County Council to undertake his own *x*-ray work, and he developed this to the highest degree of efficiency. He contributed several chapters on this subject to the annual report on the tuberculosis work in Lancashire, and an article entitled "The value of *x*-ray work in a tuberculosis dispensary" appeared in *Tubercle* in 1927. He also rendered important pioneer service in regard to the treatment of tuberculosis by artificial light at centres established in tuberculosis dispensaries. After two years' experimental work at the one in Ashton-under-Lyne he proved that this treatment was particularly valuable in the case of lupus and adenitis with abscess formation and skin involvement. In the past twelve months Dr. Stewart had devoted much time to the question of tuberculosis and silicosis, and contributed an article to the *British Journal of Tuberculosis* last January. He was engaged in further research on silicosis at the time of his death. For the following note of appreciation we are indebted to Dr. G. Lissant Cox, central tuberculosis officer to the Lancashire County Council: In the last ten or fifteen years the tuberculosis service in the North of England has had two exceptionally gifted clinical tuberculosis officers—the late Dr. W. C. Rivers, district tuberculosis officer of the West Riding County Council, and John Logan Stewart. Stewart was a typical Lowland Scot. Austere yet kind, bent but not broken by the death of his wife some three years ago, engrossed in his work, possessed of a sure judgement and an entirely unselfish nature: these qualities made him loved and respected by all his colleagues, patients, and the doctors who so frequently consulted him. Visitors from many lands went to Ashton-under-Lyne; all returned impressed with Stewart's work. But this it was which made him stand out above the crowd: woven into every part of his being, and controlling his unceasing work, was a fierce yet sane sympathy with the sufferer from tuberculosis. For such sufferers he lived, and for them he died. A colleague (J. R. K.) writes: The passing of John Logan Stewart will be regretted with particular poignancy by his old classmates of Glasgow University. One remembers the steadfast honesty of his mind and the most lovable gentleness of his manner. Whatever Stewart set his hand to he did with all his might. Many will miss his counsel, as a tuberculosis specialist, as an expert in the radiology of the chest, or in the theory and practice of ultra-violet ray treatment. But all who knew him will cherish the memory of his sterling character and of his full-hearted devotion to the cause of the suffering.

Dr. GEORGE SCARR died on February 11th, at the age of 76, after a life devoted to many kinds of public service and spent mainly at Radcliffe in Lancashire. He received his medical education at Trinity College, Dublin, where he graduated M.B. in 1884, and obtained the diploma L.M. of the Rotunda Hospital; he became L.R.C.S.I. in 1906. More than thirty-two years ago he went to Radcliffe and joined the late Dr. Gill in partnership, but found time in the course of a busy practice for energetic work in connexion with the urban district council and the St. John Ambulance Brigade. For many years he was the chairman of the local health committee; he presided over the district council from 1919 to 1921. He actively associated himself with the establishment of the Bealey Convalescent Home and its use as a maternity home. He represented the Radcliffe district on the Bury and District Joint Hospital Board; after election to the county council he became a member of its public health committee and devoted himself unsparingly to the improvement of health conditions generally, and in particular to forwarding the work of the Sick Nursing Association. In 1901 he was appointed honorary surgeon to the local St. John Ambulance Brigade and Sick Nursing Division and helped them to obtain well-equipped accommodation, which served during the war as a military auxiliary hospital, of which he became superintendent. For these services he was awarded the O.B.E. in 1920. Educational progress in Radcliffe owed much to his personal support; he was one of the strongest advocates of the establishment of the public library, and was chairman of the Library Committee. Dr. Scarr was vicar's warden of St. John's Church for more than twenty years, a lay representative to the National Assembly, and a member of various diocesan and ruri-decanal organizations. In 1917 he was appointed a J.P. for the County of Lancaster. For many years he was a member of the British Medical Association; he served on the Lancashire County Panel Committee, and was chairman of the Insurance Committee. His personal popularity and the grateful recognition of his services drew a large congregation to the funeral service on February 14th in St. John's Church.

Dr. PERCY ASHWORTH, who died at the age of 54, on January 26th, received his medical education at Owens College, Manchester. He obtained the diplomas M.R.C.S., L.R.C.P.Lond. in 1887, graduated M.B., B.S., with honours, in 1888, and proceeded M.D. and F.R.C.S. in the following year. During his distinguished career as a student he won numerous honours, including a gold medal in physiology and various medical and surgical scholarships. He had conducted for many years a large practice in Southport, and held the appointment of assistant surgeon to the Clinical Hospital for Women and Children in Manchester. He was an ex-president of the Southport Medical Society, and for many years had been a member of the British Medical Association. He had contributed articles on surgical subjects to the *British Medical Journal* and to the *Transactions of the Manchester Pathological Society.*

Universities and Colleges.

UNIVERSITY OF OXFORD.

As announced in our advertisement columns, an examination for the Theodore Williams Medical Scholarship will begin on June 4th. It is of the value of £100 a year, and tenable for four or five years. Full particulars can be obtained on application to the Senior Tutor, Pembroke College, Oxford.

UNIVERSITY OF LONDON.

THE Senate has accepted with thanks an offer by the trustees of the late Mr. C. H. Clark of £10,000 for the establishment of a lectureship in the history and progress of preventive medicine and tropical hygiene, and also a grant of £1,000 from the Beaverbrook Fund for Medical Research, forwarded by the Prime Minister. The grant will be applied to the purposes of, and administered under the scheme for, the Thomas Smythe Hughes Medical Research Fund.

Professor W. E. Le Gros Clark has been appointed, as from September 1st, to the University Chair of Anatomy, tenable at St. Thomas's Hospital Medical School.

A degree of Ph.D. has been instituted in non-clinical subjects for both internal and external students in the Faculty of Medicine.

The Geoffrey E. Duveen Travelling Studentship in oto-rhino-laryngology, of the value of £450, has been awarded for 1929 to Mr. Nehemiah Asherson, M.B., B.S., F.R.C.S.

On the recommendation of the School Committee of University College Hospital Medical School, Dr. G. R. Cameron has been appointed to the Graham Scholarship in Pathology for two years, from September 1st, 1928.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—T. A. Barnabas, C. M. Brooks, N. Das, H. W. E. Dickey, R. Frankling, K. E. Gallaher, K. Girgis (Section I).
MEDICINE.—W. A. A. Collington, H. M. Feldman, L. P. Gregory, C. K. McCoan, C. F. C. White.
FORENSIC MEDICINE.—C. W. Ellison.
MIDWIFERY.—R. K. Nandlal, C. Skinner.

The diploma of the Society has been granted to Messrs. T. A. Barnabas, C. M. Brooks, W. A. A. Collington, N. Das, L. P. Gregory, C. K. McCoan, and C. F. C. White.

Medical News.

MR. A. W. SHEEN, F.R.C.S., professor of surgery and director of the surgical unit of the Welsh National School of Medicine, will deliver the Hunterian Oration before the Hunterian Society at the Mansion House, E.C., on Monday, March 4th, at 9 p.m.; the subject is some aspects of the surgery of the spleen, illustrated by lantern slides.

A SPECIAL discussion on industrial dermatoses, their causation, recognition, prevention, and treatment, arranged by the Sections of Dermatology and Epidemiology of the Royal Society of Medicine, will take place at 1, Wimpole Street, W., on Thursday, March 21st, at 4.45 p.m. A selection of cases will be shown at 4 p.m.

UNDER the auspices of the Chadwick Trust a Malcolm Morris Memorial Address will be given by Sir Norman Walker at 5.15 o'clock, on May 16th, at the Royal Society of Arts, with Sir StClair Thomson in the chair.

THE annual general meeting of the Medical Officers of Schools Association will be held at the rooms of the Society of Medical Officers of Health, 1, Upper Montague Street, Russell Square, W.C.1, on Friday, March 15th, at 5 p.m.; tea will be served at 4.30 p.m. Sir Henry Gauvain, medical superintendent, Lord Mayor Treloar Cripples' Hospital and College, will read a paper on the combined education of children suffering from physical defects.

AN intensive post-graduate course in general medicine and surgery, including the special departments, will be held at the West London Hospital from March 11th to March 23rd. The fee for the course is six guineas. Full particulars can be obtained on application to the dean, West London Hospital, Hammersmith, W.6.

AT the East London Hospital for Children, Shadwell, E.1, interesting cases will be demonstrated by the honorary staff on Wednesday, March 6th, at 4 p.m. Tea will be served at 3.45 p.m. Medical practitioners are cordially invited.

A SPECIAL two weeks' course in orthopaedics will be given at the Royal National Orthopaedic Hospital, Great Portland Street, W., from March 11th to 23rd. The fee for the course, which is open to all post-graduates, is three guineas.

THE Fellowship of Medicine announces that on Monday, March 4th, at 5 p.m., at the Medical Society, 11, Chandos Street, Cavendish Square, Mr. Herbert Paterson will deliver a lecture on pitfalls in radiology. A demonstration will be given by Mr. E. T. C. Milligan, on Thursday, March 7th, at 5 p.m., at the St. Mark's Hospital, City Road; and on Wednesday, March 6th, at 4 p.m., Dr. S. A. Henry will give a lecture-demonstration at the Wellcome Museum of Medical Science, 33, Gordon Street, on the industrial cancers and their importance in the investigation of the problem of new growth. There is no fee for attendance at the above lecture and demonstrations. From March 11th to 23rd the Royal National Orthopaedic Hospital will hold an all-day course in orthopaedics if there are not fewer than ten entries; a course in [illegible] will be held during the same period at the Ro[illegible] consisting of clinical demonstrations each afternoon. Courses in April will deal with tropical medicine, electrotherapy, medicine, surgery and gynaecology, neurology, and a practitioner's course in general medicine and surgery lasting for an hour and a half in the late afternoon. Copies of all syllabuses, and details of the general course of work in the London hospitals associated with the Fellowship of Medicine, are obtainable on application to the secretary of the Fellowship, 1, Wimpole Street, W.1.

UNDER the auspices of the National Council for Mental Hygiene Dr. Bernard Hart will deliver a lecture on the minor mental disorders of everyday life, at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Wednesday, March 6th, at 5 p.m.

THE Royal Sanitary Institute will hold its Institute Dinner on Thursday, March 21st, at the Hotel Metropole, with the president, the Duke of Northumberland, in the chair.

DURING Easter a week's excursion for medical practitioners and their families will be arranged to the Mediterranean coastal resorts, including Cap d'Antibes, Juan-les-Pins, Cannes, Le Cannet, Grasse, Vence, Mentone, Monaco, Monte Carlo, and Beaulieu. Further information may be obtained from the president of the Société Médicale du Littoral Méditerranéen, 24, Rue Verdi, Nice.

THE Water Pollution Research Board of the Department of Scientific and Industrial Research issues periodically in typescript a summary of current literature bearing on water supplies, sewage, trade waste waters, river pollution, and kindred subjects. The issue for January has been placed in the Library of the Association, where it will be available for the use of members.

THE Savill prize (value £15) of the West End Hospital for Nervous Diseases is offered in 1929 for the best thesis on a neurological subject submitted to the examiners not later than October 31st. The prize is open to post-graduates who have attended the practice of this hospital on at least ten occasions, and candidates must submit the subject of their choice for the approval of the examiners not later than April 9th. Full particulars may be obtained on application to the secretary, West End Hospital for Nervous Diseases, 73, Welbeck Street, W.1.

DR. P. MERRIN has been unanimously appointed chairman of the Kingstown Urban District Council. This is the first time a medical man has been appointed to this office in the premier township in the Irish Free State. Dr. Merrin has acted as a chairman of the Public Health Committee for the past nine years.

AT the end of 1928 *Lijecnicki vjesnik* ("The Medical Advertiser"), the monthly journal of the Croatian Medical Society in Zagreb, celebrated its fiftieth anniversary. During its existence this periodical has developed gradually from a modest beginning, and has published 1,554 articles by 695 different authors; the rapidity of its recent growth is indicated by the fact that in 1928 it published 211 articles by 176 different authors.

THE annual congress known as the Journées Médicales de Paris will be held from June 9th to 14th. The subscription is 50 francs. Further information can be obtained from Dr. Léon Tixier, 18, Rue de Verneuil, Paris.

THE Annual Congress of the German Roentgen Society will be held in Vienna from April 20th to 22nd, under the presidency of Professor Hans Meyer of Bremen.

THE two German-Spanish journals named *Revista Medica de Hamburgo* and *La Medicina Germano-Hispano-Americana* have been united into a single organ, entitled *Revista Medica Germano-Ibero-Americana*, under the direction of the two previous editors, Professor Mühlens of Hamburg and Professor J. Schwalbe of Berlin.

DR. LUDWIG ZAMENHOF, the inventor of Esperanto, has recently celebrated his seventieth birthday.

THE following resolution adopted by the Grand Council of the National Citizens' Union has been sent to the Minister of Health: "With a view to the reduction of the numbers of mentally afflicted, unfit, and diseased persons, an inquiry should be held into the best method of dealing with mental deficiency and incurably diseased persons, including a special inquiry into the possibility and advisability of legalizing sterilization, under proper safeguards, and in certain cases"

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (*Advertisements, etc.*), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

URTICARIA AND MALTED MILK.

DR. EVA MCCALL (London, W.1) asks whether any case has been recorded of an attack of urticaria following the ingestion of malted milk. She writes: A case has recently come to my notice of a cup of malted milk being taken for insomnia about 1 a.m.; ten to fifteen minutes afterwards intense itching of the palms set in, and was followed by an outbreak of "nettle rash" on the arms, wrists, chest, and back. The eyelids were also affected. The patient in question had never taken the preparation before, and had no idiosyncrasy to any other articles of diet. The eruption cleared up in about twenty-four hours, but the patient felt very out of sorts for a day or two afterwards.

TREATMENT OF UNCONTROLLABLE COUGH.

"D. H. A." asks for advice in the treatment of a patient, aged 48, who has suffered for many years from an uncontrollable cough attended with profuse expectoration. When young he had nasal obstruction, due to enlarged turbinals, portions of which were removed; the breathing power was improved. The present condition is abundant anterior and posterior nasal catarrh and laryngeal irritability, making the coughing almost incessant. The bronchial tubes are clear. The patient is of a nervous temperament: the general health is good and there is no asthma. He has had treatment by a specialist, but to no purpose. Unfortunately he is a heavy smoker, but he objects to giving up the habit. There appears to be a vicious circle in the case. The frequency of the cough is not only a distress to himself, but to all his friends. Is this a case for hypnotic suggestion? Can any method of relief be suggested?

EMISSION WITHOUT ORGASM.

"M.B., B.S." writes: A male patient, aged 50, apparently healthy, complains that he suffers from failure of orgasm at emission; otherwise the act is normal, and can be repeated. I should be glad of suggestions for treatment.

DIPHTHERIA CARRIERS.

"H. H." writes: What is the legal position in the following case? A servant in a house has been in contact with a case of diphtheria after ten days' service. At the request of the mistress a swab is taken. Report gives Klebs-Loeffler bacilli present, there being no clinical evidence whatever. Is one bound to report such a case, and can the medical officer remove such case forthwith? From a long experience in general practice I can recall numerous errors due to relying on laboratory diagnosis alone, and I still maintain that clinical evidence should be the main basis before the subjects should lose their liberty.

*** We have referred this question to Dr. J. Graham Forbes, who makes the following comment:

The Infectious Diseases Notification Act (1889) provides the legal means *available* for the compulsory removal and isolation of a case of infectious disease, which are applied unless there are convenient facilities for isolation and treatment in a private house. In the case in question the desirability or necessity to notify a carrier of Klebs-Loeffler bacilli, presenting no clinical signs of diphtheria, must be a matter *for the practitioner personally to* decide on the particular circumstances affecting the person concerned, and in this instance her employer and those of the family with whom there is necessarily contact, particularly if there are children, in view of their greater liability to attack, when infected. Obviously it is impracticable by notification to secure removal to hospital of every diphtheria carrier, and such a course is only advisable in certain cases, on condition that the original bacteriological report has been confirmed by subsequent examination, *and*, most important of all, by the isolation in pure culture of the bacillus for *application of the virulence test.* If found virulent, then decision should be made as to the necessity for notification, and this must depend on the circumstances of the case. The Notification Act does not *legally*, I believe, apply to the carrier unless it can be said that the individual is *suffering from the disease. The notification of diphtheria* carriers is frequently a matter for arrangement with the medical officer of health, and may be dependent on his particular views and wishes. In the case in point, it would seem advisable to refer the matter to the local medical officer of health, *if* there is confirmation of the original report and if the bacilli found are proved to be virulent.

MOONSHINE?

DR. E. GERALD STANLEY (Paris) writes: Can "C. I." seriously doubt but that the moon has a very marked influence, not only on the inhabitants of "hot" countries, but on those of all others? Of course, the moon does not "shine"; she reflects to us the light of the sun and also reflects back to us our own light. Recalling the colossal upheaval of the waters of the earth which we call tides, caused by the moon, the effect of which is more than double that of the sun (7 to 3), imagination suggests terrifying possibilities as to her influence on human actions. The "harmful" action of the moon, especially in perigee, had been suggested three thousand years before Galileo; to the best of *my knowledge the only suggestion of the application to human* ills was made by Rudyard Kipling before the Royal Society of Medicine last year. If "C. I." is really interested in these awful *possibilities, he should address his inquiries to astronomers* and physicists, and, above all, to those few who still have intelligent imagination. As I reflect, a song comes back to me from my *rather younger days, "I'm such a silly when the moon comes* out." The writer of this lyric had imagination; in our pitiful ignorance why not hold speech with such, even though they only write songs for the Gaiety?

SIR JAMES BARR writes: Why does "C. I." (February 16th, p. 331) seek information from "any medical man" about moonshine? Medical men do not possess a monopoly in wisdom or knowledge on any subject. Why does he not himself investigate the truth or otherwise of what he "hears so often"? In an early number of the *Health Journal* there was a very informative article by Professor Baly of Liverpool on the effects of the polarized light of the moon on the growth of seedlings and the maturation of plants. These, of course, are beneficial effects, but, on the other hand, it is well known that polarized light reflected from the snow is seriously damaging to the eyesight of the St. Bernard dogs, so much so that it is feared that that variety of dogs may become extinct. It is not likely that the effect on human species in the East would be so serious, but we should be all pleased to hear of any reliable information which can be gathered on the subject.

DR. WINNIFRED W. BOLAND (Newry, co. Down) writes: I have just returned from a two years' stay in an up-country district in Bengal. I had my bed on a south-east corner of the verandah all the year round, except during the monsoons. The moon shone full on my face as long as it was not directly overhead, which was very rarely. I suffered no ill effects, but a friend who stayed with me for four months always took care that the moon should not shine on her face, as she once got "moonstruck." Her husband woke her up because her face was all drawn on one side and continued so for a few hours after she was roused. I never met anyone else who was "moonstruck," but I did not make any serious inquiries.

"B. H. R." (Glasgow) writes: During three years' residence in Central Africa I found that moonshine gave me a headache. I made it a practice in going out at night to put on a light pith helmet or double felt hat. I connected this harmful influence of the moon with what one reads of in the Psalms, "The sun shall not smite thee by day, nor the moon by night."

"G. A. C. G." writes: From personal experience I can say that the direct rays of the moon on a sleeper can be very disagreeable, if not actually harmful. In the Middle East such exposure caused nightmares and headaches. In the Far East these symptoms were accentuated and accompanied by a morning "thick head." Prevention entailed moving the bed or closing the shutters.

"H. M. S." writes: There is a superstition in Burma that exposure of the face and head to moonlight while in bed has a baneful effect upon one's brain, meaning mental make-up. Perhaps this is evolved from the legend that mental storms in the insane correspond to phases of the moon.

INCOME TAX.

Depreciation of Plant and Machinery.

"A. B. C." has claimed an allowance, based on 15 per cent., in respect of an electro-cardiograph. The inspector is willing to allow the cost of replacement if and when incurred, but not the percentage allowance for depreciation. In his view the electro-cardiograph is an instrument, and not an item of "plant or machinery."

*** In a fairly recent case, Daphne *v.* Shaw, decided in 1926, Mr. Justice Rowlatt said: "It is impossible to define what is meant by 'plant and machinery' . . . it means apparatus, alive or dead, stationary or movable, to achieve the operations which a person wants to achieve in his vocation." In that particular case the judge refused the allowance when claimed in respect of the appellant's professional library, but a perusal of his judgement leaves one convinced that he would have granted it in respect of the apparatus mentioned by "A. B. C." We suggest that he refer the inspector to the case quoted above.

LETTERS, NOTES, ETC.

TREATMENT OF PNEUMONIA.

DR. R. C. WORSLEY (Topsham) writes: Recent letters on the treatment of pneumonia in the *Journal* (January 5th, p. 15, and February 16th, p. 332) prompt me to record a singular case I attended recently. A man, aged 76, had, on November 26th, an attack of localized pneumonia at the right base, which I took to be influenzal, and which ended by crisis on December 2nd. On December 21st he was found to have broncho-pneumonia, involving the left base; this spread over the back of the lower lobe, the temperature ranging between 100° and 102° F. for more than a month. On the ninth day of this attack he was needled over the point of maximum dullness, half an ounce of clear fluid being removed. Three days later he was needled again, without result. A week later still I drew off two ounces of similar fluid, which was found to contain many pus cells, but to be sterile on culture. Colloid manganese injections and creosote were given until January 22nd, when a specimen of sputum was found to contain a few *Staphylococcus albus* and large colonies of streptococcus. Creosote was now pushed twice a day. From that day the temperature fell by lysis, and it has remained practically normal since. The patient was allowed to sit up for short intervals from February 2nd. I do not pin my faith to creosote in pneumonia, but I feel convinced that it exerted a striking influence on the course of the infection in this case, which, considering the age of the patient and the severity of the disease, makes his recovery remarkable. I should be interested to hear if others have seen similar good results in lobular pneumonia.

CARDIOSPASM OR ACHALASIA OF THE CARDIA.

MR. G. W. RAKE (writing from the Johns Hopkins University, Baltimore) says: I wish to correct an error which appeared in my letter to the *British Medical Journal* of December 15th, 1928 (p. 1111), on achalasia, which error was also pointed out by Mr. Beatty in a letter to the *Journal* of January 5th, 1929 (p. 45). Owing to an oversight the first series of figures supposed to be the measurements of the thickness of the oesophageal wall are in reality those of the diameter of the lumen of the specimen. The following figures are those of the thickness of the wall in the first case (the compensated achalasia):

Just below the cricoid	0.2 cm.
Middle of oesophagus	0.8 cm.
Just above the cardia	0.45 cm.

I apologize for the interval of time allowed to elapse before its correction, but unfortunately Mr. Beatty's letter has only just come to my notice.

*** This correction was made, in Mr. Rake's absence abroad, by Dr. A. F. Hurst on January 12th.

MODERN BREAD-MAKING.

DR. A. OGIER WARD (London, E.C.2), in the course of a letter, writes: Can there be any more serious procedure than to eliminate from flour the most valuable part of the grain? The question naturally arises, Why is it removed? The answer requires some lengthy explanation. When we depended on water and windmills for all our flour man could thrive on bread because he got the entire product of the grain minus the bran. Unfortunately, flour so prepared became rancid if kept too long, by reason of the oily products in the phosphatic and nitrogenous elements present, particularly in the germ. And then came the steel miller, who removed the germ and triumphantly offered a fine white flour which would keep almost indefinitely. The demand for whiten ss spread, and instinctively the labouring classes began to demand more meat. No wonder! They no longer got the nitrogenous and pho-phatic elements in their bread. There are scientists who tell us that the white flour now sold contains all essential ingredients for health. Probably it does for prosperous persons who have as much meat and other foods as they want, but growing children and the poorer classes require all the phosphates and nitrogenous foods they can get, and it is wrong t · rob them of these ingredients in their staple diet. From some well-to-do adults and from many of the ignorant poor I hear that they prefer white bread. I have yet to hear of a child who prefers it. I consider it is criminal folly to extract the most valuable part of the grain and then to buy it back, as many do, in the form of a commercial product.

HARVEY AND SCARLATINAL DESQUAMATION.

DR. J. D. ROLLESTON (London, S.W.6) writes: Referring to the statement in my paper on "The history of scarlet fever" (*Journal*, November 24th, 1928, p. 926) that Sennert was the first writer to mention scarlatinal desquamation, my friend Dr. Archibald Malloch, librarian of the New York Academy of Medicine, has drawn my attention to the following passage of Harvey's *Prelectiones Anatomiae Universalis* (p. 12), which was published in 1886, the lectures having been given probably in 1616 for the first time: "Homine porrigine meale avibus volmando scalptu animalibus equo curried the bird att St. James bemealing as a man scarlet." In their introduction to the *Prelectiones* the committee of the Royal College of Physicians interpret this puzzling sentence as a comparison of the desquamation after scarlet fever to the shaking off of the feather scales of a bird in the royal menagerie then kept at St. James.

CEREBRAL ANGIOSPASM.

DR. F. G. GARDNER (Oxford) writes: The case reported by Dr. F. J. Allen in the *Journal* of February 16th (p. 323) reminds me of one I saw some fifteen years ago. I was asked to visit a man, aged about 75, as he had had a "seizure." I found him hemiplegic, aphasic, and much confused. The urine was loaded with albumin. Hemiplegia, or other "plegias," are not uncommon in uraemia—without gross brain lesions. In this instance, with some purgation and complete rest, the paralysis completely disappeared in the course of twenty-four hours, I confess to my surprise, as I had regarded it as probably of an organic nature. I cannot say anything of the patient's after-history, as he went out of my ken. To-day, I suppose, I should call the condition "cerebral angiospasm." It would be interesting to know the condition of the kidneys in Dr. Allen's case, which seems to have been very similar to mine.

HERPES AND VARICELLA.

"R. P." (Lancashire) writes: In previous issues of the *Journal* suggestions of a relationship between herpes and chicken-pox have been made; the following case appears to have some bearing on the matter. A woman contracted herpes ophthalmia on January 10th; her son, aged 10, returned to school on the 19th, and in a few days chicken-pox developed. Her daughter, after a few days at school, also began an attack of chicken-pox; the youngest daughter did not return to school owing to a cold, and on February 4th chicken-pox developed of a more severe type than in the boy and girl at school. There is no other case of chicken-pox in the district. I should be interested to know what conclusions might be drawn from the above.

TREATMENT OF INFLUENZA.

DR. GARRY SIMPSON (London, W.2) writes: In the *Journal* of June 4th, 1921 (p. 835), Sir G. Archdall Reid of Southsea recommended for cases of acute toxaemia, pneumonia, etc., a mixture of aspirin 10 grains, phenacetin 5 grains, and pulv. ipecac. co. 5 grains, once or twice daily. For some years I have treated all cases of influenza in this way, with such satisfactory results that I would strongly advise brother practitioners to give it a trial. The patient goes to sleep and in an hour or so wakes up with a profuse perspiration, so that fresh garments must be ready to change into. The temperature falls, and the patient has intense relief from the pains, headache, etc. The powder should be repeated in six hours' time, if necessary. Most cases of influenza are cut short by this treatment in twenty-four hours.

ERYTHEMA NODOSUM.

DR. R. A. ROBERTS (Flintshire), continuing the discussion on the relation of erythema nodosum and tuberculosis, published on February 9th (p. 266) and 16th (p. 332), writes: I attended recently a family in which the mother and four children had erythema nodosum simultaneously: one child, a boy aged 14, died shortly after of acute pulmonary tuberculosis.

INFANT FEEDING.

MR. LESLIE J. HARRIS, D.Sc., writes to point out that the work described as having been done by him in the Nutritional Laboratory, Cambridge (*British Medical Journal*, February 23rd, p. 333), was actually done elsewhere, *and four years* before the inception of the Nutritional Laboratory.

OSTEOPHYTIC GROWTH IN WOMEN.

DR. J. ALEX. THOMSON (Harrogate) asks us to correct a remark attributed to him in the account of the discussion on osteo-arthritis published in the *Journal* of February 23rd. In the first column of page 353 he is reported as having said that osteophytic growth in women was rare, and that he had seen two cases only. What he did say was that extensive osteophytic growth was uncommon among women, and he then put on the screen radiograms of the two worst cases of the kind which he had been able to find among a large number of radiograms.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 53, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 51 and 52.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 55.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

203. Primary Tuberculous Pericarditis.

REMARKING that tuberculosis can occur primarily in the pericardium, J. A. CLARKE, jun. (*Amer. Journ. Med. Sci.*, January, 1929, p. 115), reports two cases of this condition and comments on eleven others gathered from the literature. Of these thirteen patients, eleven were males and two females; their ages ranged from 13 to 55. The duration of the disease is long, the shortest case lasting three and the longest twenty-two months after apparent onset. It is not necessarily fatal, and in six of the cases there was a successful arrest of the pericardial condition. Shortness of breath was the most common symptom, though cough and weakness were almost as constant, and fever was prominent in all. Pain was uncommon. Other symptoms were oedema especially marked in the face in three cases), pleural effusion, and ascites. The outstanding features of the disease are cardiac failure with fever and great increase in the cardiac outline. The diagnosis was made in seven cases from *ante-mortem* materials, and in the other six by animal inoculations with the pericardial or pleural fluids. Death occurs from heart failure or miliary tuberculosis, the latter being the more common, and it is much more frequent in this than in other forms of tuberculosis. In most cases fluid is present in the pericardial sac, and Clarke remarks that since this fluid contains viable tubercle bacilli it should be evacuated frequently. When it is impossible to effect this by paracentesis a pericardotomy should be performed. Tuberculosis should be suspected in every case of pericardial effusion, especially if it is purulent or sanguineous; in the absence of fluid, cardiac decompensation with increase in the cardiac measurements and decided fever over a long period should cause suspicion of tuberculosis.

204. Functional Albuminuria.

O. JERVELL (*Norsk Mag. f. Laegevid.*, December 1928, p. 1189), on examination of 3,507 athletes aged from 10 to 39, found albuminuria in 9.9 per cent., transient albuminuria being more frequent than orthostatic. It was very difficult, however, to draw a sharp line between the various forms of functional albuminuria. Examination during training showed that some individuals very readily had albuminuria, while others had none or only after very energetic training. A transient indisposition or chill might be the cause of albuminuria developing after an effort which would not have produced it under normal conditions. Albuminuria was more frequently observed after an effort at the beginning of training than when training had been carried on for some time. It is, therefore, advisable for an individual in whom functional albuminuria is frequently found to practise physical exercises. Examination of 112 medical students before and after a short dip in the sea at 65° F. showed that 83 did not have any albuminuria either before or after their bath, 16 had albuminuria both before and after, and 13 only after. Fractional analysis of the albuminuria and globulin in the urine showed a relatively high globulin content. Jervell states that functional albuminuria is due to the action of lactic acid on the renal tissue. Lactic acid formation is partly due to impaired circulation with resultant defective carbohydrate consumption, and partly to muscular effort. There is a certain parallelism between the excess of lactic acid in the blood and concentration of lactic acid in the urine and albuminuria. When the concentration of lactic acid in the blood exceeded 75 mg. per cent. after effort albuminuria was always found in the urine. In many cases the administration of alkalis by the mouth could prevent the appearance of albuminuria, especially of the orthostatic type. The statistics of Norwegian insurance societies show that of 72 insured persons with orthostatic albuminuria three had died of peritonitis, influenza, and chronic nephritis after six, one, and twenty-two years respectively. Jervell concludes that the presence of functional albuminuria should not exclude the individual from life insurance, military service, or sport.

205. Immunity in Dengue Fever.

G. BLANC and J. CAMIN PETROS (*C. R. Soc. de Biologie*, January 11th, 1929, p. 31) cite experimental evidence that dengue fever leaves behind it an immunity lasting for several months. In their first series of experiments they inoculated a number of persons who were convalescing, or who had recovered from dengue a few weeks previously, with virulent material (probably blood). None of the inoculated subjects developed fever, indicating that they possessed definite immunity. In their second series the authors inoculated about 70 volunteers in February and March, 1928, with virulent material; of these, 25 developed typical experimental dengue fever. In December, 1928, 20 of these successfully inoculated subjects were traced; none of them, it was found, had contracted dengue naturally during the severe epidemic in Athens of August and September. Nine of them were subjected to a second experimental injection of virus, 2 c.cm. of the patient's serum being used. None of the inoculated subjects reacted, though control persons developed experimental dengue. The authors conclude that immunity does develop after dengue fever, and they hope that it will be of a sufficient degree to prevent the occurrence of another epidemic in the summer of 1929.

206. Inoculation against Cerebro-spinal Fever.

DURING his residence at Katanga in the Belgian Congo from October, 1925, to May, 1927, BRÜYNOGHE (*Journ. de Méd. de Paris*, December 13th, 1928, p. 1005) practised vaccination against cerebro-spinal fever among the native males. Three subcutaneous injections were given in doses of 0.5 c.cm., 1 c.cm., and 1 c.cm. respectively. The results were as follows. The percentage incidence of cerebro-spinal fever was higher among the non-vaccinated than among the vaccinated, and the disease was at least ten times less frequent among those who had been vaccinated than among those who had received no injections. Inoculation conferred the greatest amount of protection in those centres where it was applied to all the natives, the incidence of the disease being greatest among those vaccinated workmen who were constantly in contact with the non-vaccinated. The author therefore recommends that the Government should take measures to enforce general inoculation against cerebro-spinal fever in places where the disease is epidemic.

207. Spirochaetosis Icterohaemorrhagica.

V. DE LAVERGNE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 15th, 1928, p. 1493) reports the case of a man, aged 43, who sixteen days after contracting a wound of the scalp, due to falling into a ditch frequented by rats, developed well-marked jaundice and epistaxis, followed by complete anuria of three days' duration. Examination of the patient's serum on the twenty-fifth day showed well-marked agglutination of the *Leptospira icterohaemorrhagiae*. There was no question of the virus having been swallowed, and infection occurred through the wound. Very few other examples of traumatic spirochaetosis icterohaemorrhagica have been recorded, though Fiessinger has reported the case of a guinea-pig which developed spirochaetosis twelve days after having been bitten by a rat.

Surgery.

208. Management of the Colostomy Case.

G. E. BINKLEY (*Annals of Surgery*, January, 1929, p. 71) gives a description of a colostomy irrigator which has been found to be very successful; it is supplied to all patients with a colostomy at the Memorial Hospital, New York, in order that they may easily undertake daily irrigation. The apparatus is composed of bakelite, and consists of a shallow cup with a wide rim; in the centre of the base of this cup is a small circular opening through which a No. 20 French catheter permits the inflow of the irrigating fluid. On one side of the cup is a large opening, a necklike projection or extension which is the outlet for the return fluid, and to this is attached a soft rubber tube which conveys the faecal fluid from the cup to a receptacle. The cup is held in place against the skin by means of four clips which are attached to a canvas belt. For irrigation the inflow catheter is inserted into the colon for three to six inches, and the irrigating can, filled with warm water or a weak solution of potassium permanganate, is placed on a stand a few feet above the colostomy. In bedridden patients the outflow is directed laterally; with ambulatory patients it is directed downwards. The fluid is allowed to flow into the colon until the latter is partly filled. The stimulated peristalsis produced by the distension expels the colonic contents, and this procedure is repeated sufficiently often to ensure the comfort of the patient for twenty-four hours. As a small amount of fluid is retained

in the colon the attachments of the cup are then changed, the inflow catheter being withdrawn and the opening closed by a threaded plug; the outflow tube is removed and replaced by a short bag, the irrigating cup thus forming a colostomy bag. This is worn for half an hour, when it can be replaced by a few layers of sterile gauze over the opening to absorb the small amounts of exuded mucus; the pad is held in place by adhesive straps or a binder. A corpulent patient is fitted with an abdominal support, which prevents any abdominal hernia about the artificial opening.

209. Heterotopic Ossification.

B. FREJKA (*Journ. Bone and Joint Surg.*, January, 1929, p. 157) remarks that under certain pa.holog cal conditions bone may be developed in soft tissues, distant from the skeleton. According to Leriche these new formations depend on two conditions: (1) the presence of embryonic tissue, an undifferentiated tissue with well-develo,ed intercellular substance and tender fibrils, or (2) a local increase in the amount of lime salts. Ossification is rare when the first condition exists by itself. A case of myositis ossificans progressiva is reported which developed in a patient with arthritic predisposition and with a congenital microdactylia of both great toes. The malady began as an attack of acute rheumatism and led to entire ankylosis of the spine and formation of extensive bony layers, which embraced the thorax and connected it by bony ridges to both humeri. After the disappearance of the last acute symptom the condition of the patient remained unchanged. The *x*-ray picture showed a diminished hypophyseal fossa. The sudden onset in this case confirms its inflammatory origin, and the influx of lime salts was aided by inflammatory infiltration of the entire thoracic wall with large absorption of adjacent bones. Many reported cases have developed without any visible causes, such as after infectious diseases, traumata, or transverse lesions of the spinal cord; such cases must be considered as the same malady with the same *dystrophic constitution, which is possibly due to an* altered metabolism caused by endocrine disturbance. The mode of new bone formation is explained in Leriche's theory. The bone is not formed by osteoblasts, the cells being only modified connective tissue cells, which may appear secondarily in any situation. According to Münchmeyer the course has three stages: in the first, embryonic infiltration occurs; in the second, fibrous condensation appears and the tumour becomes harder; in the third, ossification develops. Myositis ossificans circumscripta should be distinguished from the progressive type. It is usually observed in fractures after traumata and inflammations, and is of two distinct forms: in one the new bone develops in contact with bone, in the other it forms away from the skeleton.

210. The Site of the Bleeding Point in Epistaxis.

G. B. MCAULIFFE (*Med. Journ. and Record*, January 2nd, 1929, p. 6) urges the importance of carefully determining the position of the bleeding point in epistaxis before resorting to plugging. In order of frequency the haemorrhage is traceable to: (1) Kiesselbach's (or Mackenzie's) area, an inch behind and above the nasal spine; (2) the upper portion of the nose near the root of the middle turbinate in arteriosclerotic cases; (3) the middle of the septum from the presence of polyps; (4) the convexity of the inferior turbinate or the floor three-quarters back; and (5) from scattered naevi throughout the nose. Compensatory bleeding from the ethmoidal veins or from the inferior turbinate deep in the nose may occur in elderly people with high blood pressure. While plugging may be the only means of arresting haemorrhage from an unknown site, and its adoption necessitated by the need for obtaining immediate results, its potential dangers from secondary sepsis must be borne in mind; when unavoidable a soft dilatable rubber balloon may be used or gauze strips; in the Symes method a string two feet long is tied at its centre to the tip of a soft catheter, which, after being oiled, is passed through the nose, one end of the string being brought out through the mouth. To the middle of this a pledget of gauze is tied and pulled to the back of the nose by the nasal string, which is held tight while the anterior portion of the nose is packed. The author always administers a saturated solution of calcium lactate.

211. Acute Appendicitis simulating Strangulated Hernia.

C. WEBER (*Zentralbl. f. Chir.*, January 5th, 1929, p. 17) describes the case of a male infant, aged 5 weeks, admitted with a diagnosis of "gastric catarrh and orchitis." Three days earlier vomiting commenced, accompanied by redness and swelling of the right half of the scrotum. The child was pale and thin; there was distinct abdominal distension and faecal vomiting. A cord-like swelling extended from the external ring to the scrotum, in which there was definite fluctuation at the lower part; a strangulated right inguinal hernia was [illegible]d. The child's condition was so bad that Weber decided to perform immediate herniotomy with resection of the bowel under ether anaesthesia. On opening the hernial sac it was found to contain the caecum and the gangrenous perforated appendix, from which pus was escaping. The appendix was removed and the apparently healthy bowel was replaced, the operation being completed by Girard's method. The child made a good recovery. Although an inflamed appendix has been found frequently in a hernial sac, Weber has not discovered any previous record of gangrenous appendicitis in so young a child.

212. Pneumococcal Orchitis.

M. MIRAGLIA (*La Pediatria*, January 1st, 1929, p. 40) reports a case of orchitis occurring in a child aged 2 months. Six days previously he had been exposed to infection from a sister who suffered from a pneumococcal infection of the lung. The boy when admitted to hospital had an inflamed testicle which was evidently suppurating; the abscess was opened, and on culture the pneumococcus was recovered. The child showed no other manifestation of pneumococcal infection. Discussing the mode of infection, the author concludes that it came about through the blood. The prognosis as regards testicular function in the future is regarded as uncertain in this case.

Therapeutics.

213. A Mercurial Diuretic.

M. H. BARKER and J. P. O'HARE (*Journ. Amer. Med. Assoc.*, December 29th, 1928, p. 2060) describe the use of a relatively non-irritating mercurial preparation called "salyrgan" as a diuretic in various forms of oedema, ascites, and pleural effusion. This preparation is a 10 per cent. solution of mercury-salicylallylamide-ortho-acetate of sodium. It has been used clinically as an antisyphilitic as well as a diuretic medicament, and the initial dose is stated as 0.5 c.cm. given intravenously; subsequent doses rise quickly to 1.5 or 2 c.cm., injected once or twice a week. According to Bernheim this preparation is no less efficient than merbaphen, and in 1,000 injections he has not observed even slightly toxic effects. The present authors claim that salyrgan is particularly valuable in circulatory failure, and in the ascites due to cirrhosis of the liver and chronic nephrosis; it may also be of great benefit in the ascites of malignant and inflammatory origin. It seems to be more effective in the presence of acid-forming salts, such as ammonium chloride or ammonium nitrate, in doses of 8 to 15 grams a day. The diuresis begins in about one to four hours and is complete in from eight to twelve hours. The drug is therefore best given in the morning, since otherwise the patient may lose much sleep from frequency of micturition. The authors add that salyrgan failed to give a diuresis in only four cases, the first being a moribund patient with mitral stenosis, aortic insufficiency, and marked congestive failure; the second, a case of hypertensive vascular disease and myocardial insufficiency, with marked pitting oedema and moderate ascites; the third was a case of mitral aortic stenosis; and the fourth a case of hypertensive vascular disease, with myocardial insufficiency and marked pitting oedema and ascites.

214. Intravenous Injection of Calcium Chloride in Acute Epididymitis.

ZUNG-DAU ZAU (*Nat. Med. Journ. of China*, December, 1923, p. 368) records 58 cases of acute gonorrhoeal epididymitis treated in the genito-urinary clinic of the Pekin Union Medical College by intravenous injection of calcium chloride. According to Zau the calcium acts (1) by increasing leucocytosis and so favouring absorption of inflammatory products, and (2) by its depressant effect on the central nervous system, and possibly on the peripheral system also, as suggested by the numbness of the arm following accidental extravasation into the tissues. In the cases first treated 5 to 10 c.cm. of a 10 per cent. solution was the dose; later 15 to 25 c.cm. of a 2 per cent. solution was used. One to five injections were given in this series of patients, and relief of pain was noted in two to twenty-four hours in most instances. In only one case was there no benefit from the treatment. In twenty-seven cases subsidence of swelling or diminution of tenderness occurred on the day of the first injection. The interval between injections ranged from two to five days in most cases, but sometimes they were given daily. Zau's series included two cases of prostatitis and three of arthritis. The majority of cases were ambulatory, and supplementary treatment by local applications and suspensory bandages were also employed. It is stated that toxic effects may be avoided if the injection is given slowly, and that the occurrence of superficial gangrene of the skin is an accident only to be found when the technique of injection is faulty.

215. **Serum Therapy in Chronic Ulcerative Colitis.**

J. A. BARGEN (*Arch. Int. Med.*, January, 1929, p. 50) reports a series of cases of chronic ulcerative colitis in which definite improvement in the general condition followed deep muscular injections of a concentrated immunizing serum prepared from the diplo-streptococci which he isolated in 1924. In seven cases of acute fulminating ulcerative colitis two patients completely recovered, and have remained so, while in the other five the pyrexia ceased and the melaena decreased or disappeared, though slight symptoms remained. Two patients died, one after benefiting definitely from serum treatment. Bargen noted a significant increase in the weight of the patients soon after the administration of the serum had begun, and concludes that neutralization of the toxins is brought about; this is also indicated by the fall in the temperature and the improvement of the pulse. Proctoscopic and radiological examinations similarly showed that this serum acted effectively on the mucous membrane of the colon. Bargen adds that further work on the immunization of horses by these diplo-streptococci is being continued at the Mayo Clinic, and it is hoped that the serum will be rendered still more effective.

Disease in Childhood.

216. **Children's Diseases in the Tropics.**

B. NOCHT (*Monats. f. Kinderheilk.*, December, 1928, p. 217) states that infantile mortality is extraordinarily high in the tropics. In certain regions, such as the former German East Africa, it ranges between 30 and 80 per cent. of all children born alive. The causes of the high mortality are, first, the unsuitable feeding of the children during the first years of life; secondly, diseases due to chill; and, thirdly, infectious diseases. Native children are all breast-fed from birth until the fourth or fifth year, but they are also given all sorts of food, such as mashed bananas or potatoes, which has previously been masticated by the mother. Respiratory diseases are particularly common and fatal in mountainous districts, where clouds, rain, and cold are frequent. The children in these parts run about naked or very inadequately clad. The most prevalent infectious diseases are small-pox, whooping-cough, dysentery, measles, and malaria; scarlet fever and diphtheria are almost unknown. That the high infantile mortality is not due to the climate, but to the poverty and ignorance of the native people, is shown by the excellent results obtained by missionaries with welfare work and education. The diseases which principally attack children in the tropics and run a peculiar course when they do attack them are beri-beri, which exclusively affects breast-fed children, trypanosomiasis, yellow fever, which usually runs a mild course in children, Leishmaniasis, intestinal parasites, and bilharziasis.

217. **Diagnosis of Tuberculous Pulmonary Glands.**

F. PÉCHAUD and P. LAMOTHE (*Gaz. Hebd. des Sci. Méd. de Bordeaux*, December 2nd, 1928, p. 773), as the result of observations made at the Xavier-Arnozan Sanatorium, near Bordeaux, discuss the diagnosis of tuberculous pulmonary glands in children between the ages of 2 and 13. They found that in 55 per cent. of their cases one parent was tuberculous. Among childish ailments measles most frequently appeared as the antecedent illness which weakened resistance to tuberculosis. After an epidemic of measles in the sanatorium four cases changed from latent to fulminating tuberculosis. The classical description of a scrofulous child did not invariably apply. Fever was one of the most important diagnostic symptoms. No particular type could be described; it was not the height of the evening temperature which counted, but rather the amplitude of the oscillation. The sputum was almost invariably positive when it was obtained. Physical signs, so clear and so important in adults, were much more protean in children, and therefore difficult to interpret. Palpation in the cervical and substernal regions might reveal any stage of enlargement of the glands. By auscultation it was often difficult to distinguish between the reaction of the peribronchial glands and actual loss of parenchymatous tissue. An *x*-ray examination was made in 100 cases; 17 thoracic images were normal, in 17 the hilum was definitely affected, 11 showed some reaction round the hilum, in 19 the hilum was more marked than normal but apparently not pathological, and in 20 one or more lobes were affected. The skin reaction was regarded as only of secondary importance after early infancy. Acid-fast and alcohol-fast bacilli were frequently found in the stools. In establishing the presence of the tubercle bacillus in the organism, the authors attach primary importance to radioscopy, radiography, and examination of the sputum and stools.

218. **The Preventorium Child.**

I. D. BRONFIN (*Amer. Journ. Dis. Child.*, November, 1928, p. 931) reviews the clinical features of the pre-tuberculous child. The positive tuberculin reaction constitutes the indisputable evidence of infection, but the child may be, and often is, well nourished and apparently free from active disease. In the majority of instances the child is unhampered throughout life by the latent infection; in some cases, however, miliary tuberculosis or tuberculous meningitis develops. The cases under review comprised a group of 300 children from 2½ years to 16 years of age in a preventorium; 57 per cent. were males and 43 per cent. females. Deficiency in weight of 7 per cent. or more was found in 70 per cent. In 45 per cent. definite cervical or submaxillary lymphadenitis was noted. In 30 per cent. fever was a prominent symptom. An appreciable difference was not observed in the symptomatology or physical signs between tonsillectomized and the non-tonsillectomized groups. The greatest incidence of clinical disease and positive physical signs was noted in those with a history of definite exposure. Physical signs were often negative when the history and symptoms pointed to active disease. *X* ray examination was of the greatest aid in diagnosis when correlated with the other symptoms. The difficulty is stressed of diagnosing tracheo-bronchial tuberculosis, which in this series was frequently responsible for active symptoms. The author advocates the provision of preventoriums for the observation of children who have been exposed to infection, and for the treatment of juvenile tuberculosis.

Obstetrics and Gynaecology.

219. **Hysterosalpingography.**

H. NAHMMACHER (*Surg., Gynecol. and Obstet.*, January, 1929, p. 33) reviews the possibilities of hysterosalpingography as a diagnostic and therapeutic measure. The use of a 40 per cent. lukewarm solution of iodipin has been found to cause no inflammatory changes or detrimental results either to the peritoneal cavity or to the mucous membrane of the uterus and tubes; a very clear picture of the actual anatomical relations can be obtained. With the pelvis raised and a 30° angle of inclination of the Roentgen tube highly satisfactory radiograms result; the author advises closing the cervix after injection to prevent the iodipin escaping and to assist its penetration into every angle of the uterus and tubes. Not only has salpingography been found to be an unequalled diagnostic means in the study of sterility, but since the injections may release delicate occlusions of the fimbriated ends of the tubes they may have a decided therapeutic value. Radiograms of the uterine cavity have an additional diagnostic value in cases of uterine tumours when other measures of examination fail to give exact data. In all cases of fresh tubal infections, however, uterine examinations by this method are contraindicated because of the possibility of causing injury which would not result from mere manipulation. The recognition of such limitations to the use of salpingography is not difficult, since other methods of examination indicate clearly these unsuitable cases. Since it was found that filling the uterine cavity with iodipin in the early months of pregnancy did not lead to abortion, hysterograms in selected cases may be of use in the early diagnosis of intrauterine pregnancy; in genital fistulae salpingography is of value in clearly demonstrating anatomical relations, determination of which by using a sound might lead to injury

220. **Chorea Gravidarum.**

ACCORDING to A. M. CAMPBELL (*Amer. Journ. Obstet. and Gynecol.*, December, 1928, p. 881) chorea in its major form is one of the rarer complications of pregnancy; there is ample evidence that it is an infection with a predilection for the basal ganglia of the brain and for the endocardium, more particularly the mitral valves. A neuropathic temperament and hereditary history have been noted in many cases. Streptococcal infections, such as scarlet fever, acute rheumatism, or endocarditis, often precede chorea gravidarum. In one series of 50 necropsies valvular lesions were found in 66 per cent. The disease is more common among young women, especially primiparae. After an extensive review of the literature Campbell concludes that all cases of chorea gravidarum are of infectious origin, as are the endocarditis and arthritis that usually accompany the cerebral lesions. Pathological inflammatory changes are found in the brain, especially in the basal ganglia. Conservative treatment will suffice in the milder cases, but labour must be induced in the extremely severe forms; Caesarean section may be performed when the child is viable. Campbell remarks that all obstetricians should realize the dangers of chorea gravidarum to both mother and child. Pre-natal care, especially

directed to removal of all foci of infection whenever practicable, and also to the management of the neurotic patient in order to secure mental and physical rest, should reduce the incidence and severity of this disease.

221. The Pyramidon Test in Interrupted Ectopic Pregnancy.

According to S. M. KLEIN (*Arch. f. Gynäk.*, November 13th, 1928, p. 255) examination of the blood serum by the pyramidon test is a valuable diagnostic aid in cases in which the clinical history and signs point to the possibility of interrupted ectopic gestation. The test, applied to examination of the blood serum by Autoschina, probably indicates the presence of small amounts of haematin derived from the intraperitoneal haemorrhage. One drop of serum is added to a mixture of 3 c.cm. of a 5 per cent. solution of pyramidon in 96 per cent. alcohol, 8 drops of 50 per cent. acetic acid, and 8 drops of 3 per cent. hydrogen peroxide solution. A positive result is shown by the appearance within twenty minutes of a light blue, deep blue, or violet coloration, and is obtained in 90 per cent. of cases of interrupted tubal pregnancy. A coloration is to be expected when the patient is menstruating, and Klein also obtained a positive result in two cases of ovarian apoplexy. In 36 cases of childbirth, uterine abortion, and adnexal inflammatory tumours a negative reaction was obtained in 30, a doubtful in 4, and a positive in only 2.

222. Tuberculous Salpingitis.

G. VAN S. SMITH (*Amer. Journ. Obstet. and Gynecol.*, November, 1928, p. 701) analyses 63 cases of tuberculous salpingitis, in which the diagnosis was made or confirmed microscopically, and which gave the low incidence of 0.48 per cent. among 13,000 laparotomies, and 2.26 per cent. among laparotomies for tubal inflammation, in one gynaecological clinic. Only three patients were aged less than 20, and only four more than 40. A past history pointing to extragenital tuberculosis, or a family history of tuberculosis, was given by one-fifth of the series. Two-thirds reported pain in the lower part of the abdomen, and one-third backache; menstrual abnormalities appeared to be absent in one-fifth, and acquired dysmenorrhoea was reported in one-half. Premature cessation of the menses was present in two patients only, aged respectively 19 and 32; metrostaxis in nine only. Of 55 married patients, two-thirds had never been pregnant. Signs of probable pulmonary tuberculosis were detected in one-fifth of the series. In one-fourth there was coincident tuberculous disease of the peritoneum, and the ovary and endometrium were each affected by tuberculosis in a like proportion of cases. No definite conclusion is drawn from the results of various operative treatments, but conservative operation on early or moderately severe cases did not give satisfactory results and was never followed by pregnancy.

Pathology.

223. The Bile Acids in Jaundice.

I. KATAYAMA (*Arch. Intern. Med.*, December, 1928, p. 916) reports further studies of bile acids in the blood and urine in a series of 32 cases representing different types of jaundice. In normal controls the icterus index ranged from 4.4 to 7.0, the average being 5.7, and van den Bergh's bilirubinaemia test was negative in all except one, in which the indirect reaction was weakly positive. The bile acids of the blood serum ranged from 5 to 12 mg. per 100 c.cm. estimated as sodium glycocholate, averaging 7 mg. Tests for urobilin excretion and for bile acids in the urine were negative. In patients with cholecystitis, disease of the liver, catarrhal and obstructive jaundice, cardiac decompensation, and duodenitis a marked increase in the bile acids of the blood serum, accompanied by their urinary excretion, was found. Katayama states that the changes in the concentration of bile acids in the blood bear no relation to variations in the bilirubin content of the blood; he found that the bile acids appeared in the urine when their concentration in the blood serum exceeded 20 mg. per 100 c.cm. While acute obstructive or catarrhal jaundice caused the bile acids of the blood to rise rapidly from about five to seven times the normal, in chronic obstructions such increase was only three or four times the normal. This smaller concentration of bile acids in the blood in chronic obstructions may be explained as follows. Since the production of bile acids in the body is limited, and since normally they are excreted into the intestine to be reabsorbed and circulated again, their amount in the body is kept constant; in a long-standing obstructive jaundice, however, there is a continuous excretion of bile acids by the kidney without any reabsorption, thus depleting their store in the body.

224. The Thyroid Function in Graves's Disease.

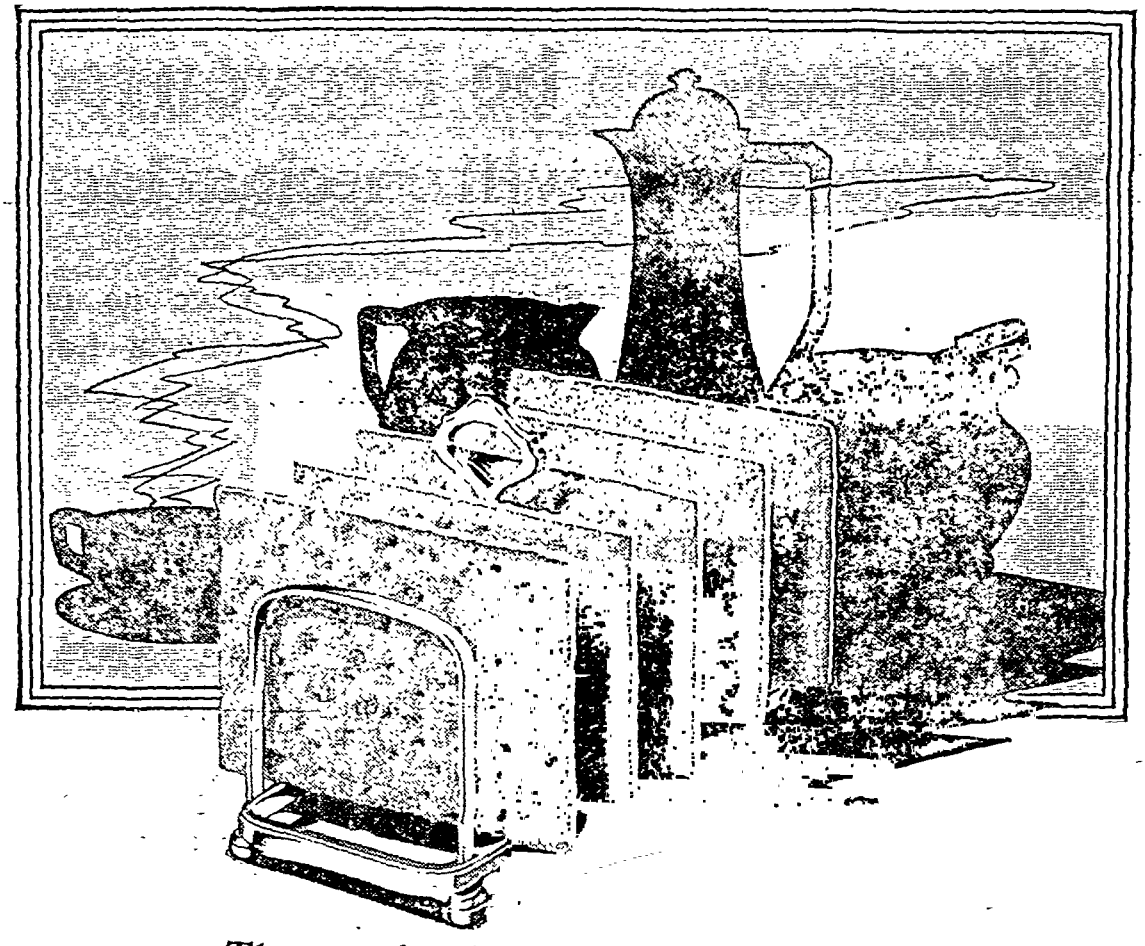
G. S. WILLIAMSON and I. H. PEARSE (*Quart. Journ. Med.*, October, 1928, p. 21) produce evidence, drawn from a study of the therapeutics of Graves's disease, bearing on the two functions in the physiology of the thyroid—the secreting and the iodo-colloid. The report deals only with material taken from cases of Graves's disease treated by partial removal of the thyroid gland: (1) the non-iodized group, consisting of 403 cases, in which iodine treatment was carefully excluded, and (2) the iodized group, containing 104 cases, in which pre-operative iodine treatment was consistently used. Only such cases were considered in which operation was necessary and in which the full clinical syndrome of exophthalmos, tachycardia, tremor, wasting, and smooth goitre was present. The authors state that the secretory activity of the gland may occur in diffuse or circumscribed areas scattered throughout the gland, alongside which there may be abundant iodo-colloid formation. The two functions are not mutually derivative, but their relation to Graves's disease is shown by the following findings. The secretory activity of the gland is directly related to the thyrotoxicosis of the disease, which can be relieved by the removal of the secreting tissue; the iodo-colloid function bears only an indirect relation to the thyrotoxicosis. An absolute loss of a thyroid reserve of iodo-colloid can occur; this happened in 48 per cent. of the cases. The mobilization of colloid depends upon some factor in the secretion, since, when iodine feeding is excluded, excision of pure secreting tissue allows a reserve of active normal iodo-colloid to reappear in the remainder of the gland. Iodine feeding can also re-establish a reserve of normal active iodo-colloid in the gland, though such re-establishment does not abolish the thyrotoxicosis. There is no absolute lack of circulating iodine, but a relative lack may complicate the disease; while such a relative lack is relieved by iodine feeding, the effect on the thyrotoxicosis is not yet certain.

225. The Frequency of B. coli and B. aerogenes in Water and Faeces.

J. E. MINKEWITSCH, N. A. TROFIMUK, and S. A. WEDENJAPIN (*Zeit. f. Hyg. u. Infektionsk.*, December 15th, 1928, p. 348), working at Leningrad, have endeavoured to confirm the work of the Americans on the relative frequency distribution of *B. coli* and *B. aerogenes* in water and in faecal material. According to American workers *B. coli* is pre-eminently a faecal organism, and is not usually found in soil; whereas *B. aerogenes* is pre-eminently a soil organism, and is uncommon in faeces. The two organisms can be separated by their reaction in certain differential tests; thus, while *B. coli* gives a positive methyl red and a negative Voges-Proskauer reaction, and will not grow in a sodium citrate medium, *B. aerogenes* gives a negative methyl red and a positive Voges-Proskauer test, and will grow in a sodium citrate medium. The Russian workers have followed the American technique except in one important particular: instead of isolating their coliform organisms from water on a lactose medium incubated at 37°C., they have incubated their media at 46°C., according to the Eijkman-Bulir technique. Their coliform strains from faeces were isolated on endo and Drigalski media. Altogether they have examined 510 strains from water and 490 strains from human and animal faeces. Of the water strains 95 per cent. formed gas in lactose at 46°C., and of the faecal strains 94.5 per cent.; since *B. aerogenes does not form gas at* this temperature, this means that all the gas-forming strains were *B. coli*. By the American tests 98.2 per cent. of the water strains and 95.9 per cent. of the faecal strains proved to be *B. coli*. These results indicate that the relative distribution of coli and aerogenes in water and faeces is almost identical. They are frankly in disagreement with those of the American workers; but this may be due to the different technique used in isolation. The authors conclude that the Eijkman-Bulir method is perfectly satisfactory in differentiating *B. coli* and *B. aerogenes*, and that there is no advantage in using the more complicated American methods.

226. Movements of the Duodenal Contents.

R. W. A. SALMOND (*Radiology*, December, 1928, p. 453), employing *x*-ray examinations following an opaque meal of barium sulphate suspended in malted milk at body temperature, has observed the following movements in the normal duodenum after the age of infancy: (1) peristalsis and antiperistalsis of the cap, usually called contraction of the cap; (2) peristalsis and antiperistalsis of the second and third parts; (3) segmentation or mixing movements of the second and third parts; and (4) forward movements *en bloc*, due to the downward inspiratory movement of the diaphragm, especially affecting the second part. These have been seen not only in normal cases, but also in various pathological conditions of the stomach, duodenum, appendix, and gall-bladder.



The perfectly filled Toast Rack holds only "Ryvita Crispbread"

RYVITA CRISPBREAD — the wonderful daily bread of Sweden—is made of rye and nothing but rye, the only cereal from which the true "crispbread" can be made.

Many thousands of British doctors and dentists recommend "Ryvita" and use it in their own homes as a veritable bread of life and health.

The enthusiastic welcome and instant adoption of "Ryvita Crispbread" by food experts and the public has led to the astonishing success that has by now firmly established "The Ryvita Crispbread Habit" in our country.

"Ryvita," for every bread use, helps to make indigestion, constipation, malnutrition and obesity unknown. Yet . . . so unique is this wonderful bread that it is almost impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade and you will discover an almost unbelievable improvement on your old time breakfast toast. "Ryvita" makes you fit and keeps you slim.

Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb. 10d.

"RYVITA CRISPBREAD"

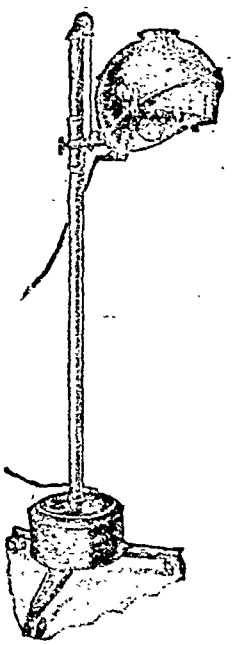
Influenza can be Prevented!

Early treatment will check attacks

In fighting influenza you can have no more valuable ally than a Hanovia Quartz Lamp. A short course of irradiations often ensures immunity to infection.



One authority recently stated:

> "In many cases I observed the increased resistance of the body to disease after ultra-violet treatment. Subjects very greatly predisposed to colds and infection were completely safeguarded after six to ten quartz light treatments."
>
> (Dr. C. B. H————, Hanover.)

The excellent results of treatment with the Hanovia Quartz Lamp in checking attacks of influenza in the early stages are classical. As far back as the influenza epidemic of 1918 the following statement was published by Dr. V. HUFNAGEL:

> "I should like to point out, from observations extending over many years, that general irradiation with the quartz lamp (Original Hanovia) not infrequently cuts off an attack of influenza in the early stages. The procedure I advise is irradiation of the body on both sides for two successive days (three at most), with exposure of two minutes each (increasing to three) at an initial distance of 28 inches (afterwards decreased to 20). Rest is essential after the treatment."

The HANOVIA ALPINE SUN

The Standard Outfit for general irradiation:

Direct Current Model - *£22 10 0*

Alternating Current Model - *£38 0 0*

PRACTITIONERS' PROBLEMS No. 7

211

Relief for Chronic Backache Through Proper Support

CHRONIC low back pain, physicians agree is, in the majority of cases, due to a lumbosacral or sacro-iliac lesion.

Study of the relationships of the bony structures of the lower back to each other and to the attached ligaments and muscles, has shown how readily trauma may occur.

Heavy lifting or pushing, especially when the torso is bent or twisted, bad posture, difficult childbirth or any other condition which creates abnormal tension in the muscles or ligaments of the sacro-iliac or lumbosacral regions may cause low back injury and pain.

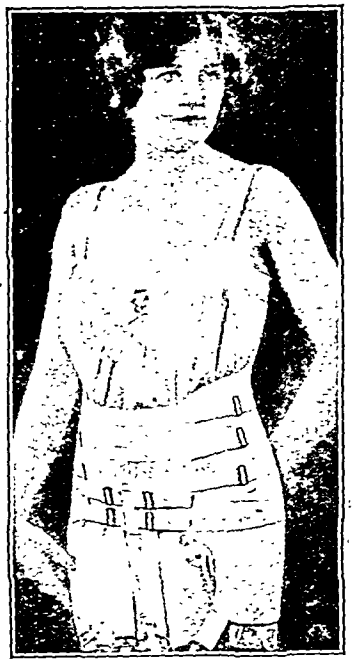
Cases so caused can be satisfactorily dealt with by the immobilization of the articulations involved.

After the area of tenderness has been determined, the physician can secure fixation of the lumbar or sacro-iliac joints by the use of a Spencer belt or corset designed with a lumbosacral or sacro-iliac pad, which acts as a fulcrum in securing proper adjustment.

With the bony structure held in position, the bruised or strained ligaments are relieved of tension or pressure, and the return to normal condition hastened.

Each Spencer support is especially designed for the patient who is to wear it. The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue booklets on the use of Spencer Supports for the relief of sacro-iliac strain, hernia, enteroptosis, movable kidney, and for maternity wear. We will gladly send you any of them in which you are interested.



Spencer Sacro-iliac Belt

The belt shown in the illustration is designed from special measurements and figure description for the individual who is to wear it.

Spencer Sacro-iliac belts are made for both men and women.

DOCTORS

prescribe "ARDENTE"

because they know it is fitted from a wide range of distinct types—very inconspicuous—devoid of extraneous buzz—true-to-tone for conversation, music, church, theatre, public and school work. They also know that the guaranteed "Ardente" carries a genuine "after-sale-service"

for their *DEAF* patients

Every important Medical Journal in the land has commended Mr. R. H. DENT'S world-famous aid for its efficiency and simplicity, and, if greater proof were required, it lies in the fact that

many DEAF DOCTORS use "ARDENTE"

"ARDENTE" STETHOSCOPE.—Mr. R. H. Dent also makes a stethoscope specially for members of the medical profession suffering from deafness, slight or acute. Many are in use, and excellent results are reported.

EFFICIENT TRUSSES BY POST

In many instances the Medical Man is faced with the impossibility of sending his patient to a skilled Truss **Maker** on the grounds of ill health, absence from employment, or cost of travelling.

Saltair Surgical Service has overcome this difficulty by fitting a patient with an "**Efficient Truss**" to his own doctor's prescription.

The special order forms we supply give us sufficient information, even in difficult or abnormal cases, to supply a spring of correct strength and shape, to cover and pad it as required, and to fit an adjustable pad of the correct size and shape. Hence, we supply by post to the doctor a Truss which is an accurate interpretation of his prescription.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent

Salary £300 per annum, subject to deductions under the Poor Law Officers' Superannuation Act.

Candidates must have had good experience in Radiography, X-ray treatment, development of plates and films, keeping of X-ray films and records, etc.

Forms of application may be obtained by sending a stamped addressed foolscap envelope, which must be returned to me at the undermentioned address by not later than 10 a.m. on Monday, March 11th.

By Order.

Guardians' Offices, 394, High Street, Lewisham, S.E.13. February 19th, 1929.

W. R. OWEN, Clerk to the Guardians.

Shanghai Municipal Council.

PUBLIC HEALTH DEPARTMENT.

ASSISTANT PATHOLOGIST.

An Assistant Pathologist is required in the Public Health Department of the Shanghai Municipal Council.

Candidates, preferably unmarried, should not be more than 30 years of age, and must hold qualifications in Medicine and Surgery of University standard; a D.P.H. and D.T.M. & H., though not essential, are desirable.

Salary, Taels 650 per mensem, under three years' agreement, renewable at a higher salary in the event of satisfactory services. First-class passage is given with half pay during voyage.

Eight months' leave is given on full pay, with first-class passage, after every period of five years' service in Shanghai.

Free medical attendance is provided, and there is participation in the benefits of a Superannuation Fund.

A Tael at the present rate of exchange equals about 2/7. Exchange is, however, subject to fluctuation.

Particulars of the appointment and full details as to the benefits enjoyed by Municipal employees under their terms of service may be obtained from the Council's Agents.

Applications, in candidate's own handwriting, with full information as to the qualifications and experience, etc. accompanied by at least three recent testimonials, and endorsed "Assistant Pathologist" on the cover, should be forwarded to—

JOHN POOK & COMPANY,
63 Fenchurch St., London, E.C.3. Agents for the Municipal Council of Shanghai.
February, 1929.

Liverpool. Town Clerk.
February 23rd, 1929.

Birmingham Public Health

DEPARTMENT.

TUBERCULOSIS SECTION.

Applications are invited for the appointment of an ASSISTANT MEDICAL OFFICER from single male medical practitioners. The duties include both Sanatorium and Dispensary work. Special experience in the treatment of Bone Tuberculosis is essential. Applicants should have been qualified for three years, and it would be a recommendation if a resident general Hospital appointment has been held. The candidate appointed will be required to pass a medical examination in connection with the Municipal Superannuation Scheme. Salary at the rate of £450 per annum, with board, residence, and laundry, estimated for superannuation purposes at £150. Applications, with copies of three recent testimonials, stating age, qualifications, and experience, should be received not later than March 9th by the Chief Tuberculosis Officer, 44a, Broad Street, Birmingham.

Oldham Union.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Guardians are about to appoint an additional Resident Assistant Medical Officer (lady) at the POOR LAW INSTITUTION, Rochdale Road, Oldham, and invite applications for the position from duly qualified persons.

Salary (inclusive) £200 per annum, with apartments, rations, laundry, and attendance, valued for the purposes of the Poor Law Officers Superannuation Act, 1896, at £90 per annum. Deductions at the rate of 2 per cent. per annum will be made from the salary and emoluments, in accordance with the provisions of the Act referred to.

The appointment is for the period ending March 31st, 1930, and is subject to termination during such period by one calendar month's notice on either side.

Copies of the duties applicable to the office, and any further particulars, may be obtained from the undersigned, to whom applications, stating age, experience, and qualifications, and accompanied by copies of three testimonials of recent date, must be sent not later than Tuesday, March 12th.

Union Offices, FRED. W FLETCHER,
Rochdale Road, Clerk to the
Oldham. Guardians.

E. W. OSBORN, Secretary.

Durham County Council and CHESTER-LE-STREET URBAN DISTRICT COUNCIL.

APPOINTMENT OF DISTRICT TUBERCULOSIS MEDICAL OFFICER AND MEDICAL OFFICER OF HEALTH.

Applications are invited for the above appointments. Candidates must be registered in the Medical Register as holding a Diploma in Sanitary Science, Public Health, or State Medicine, and must have had satisfactory experience in the diagnosis and treatment of Tuberculosis.

The County Council will pay a salary of £500 per annum, rising by annual increments of £25 to a maximum of £550 per annum, for the post of District Tuberculosis Medical Officer, and both appointments will be subject to six months' notice on either side.

Travelling and subsistence expenses according to scale will be paid by the County Council in respect of the duties of the District Tuberculosis Medical Officer.

The Chester-le-Street Urban District Council will be prepared to appoint the person selected by the County Council for appointment as District Tuberculosis Medical Officer as their Medical Officer of Health and to pay a salary at the rate of £200 per annum.

It will be a condition of appointment that if either post is terminated the other appointment will also be automatically vacated.

The appointments will be subject to the approval of the Minister of Health, and will require the whole time of the person appointed, who will not be allowed to engage in private practice.

The person appointed will be required to live in or near Chester-le-Street.

Applications, accompanied by copies of not more than three recent testimonials, must be addressed to the County Medical Officer, Shire Hall, Durham, and must be received by him not later than the first post on March 13th.

J. ROWSE MITCHELL, Secretary.

WEST AFRICAN MEDICAL STAFF

VACANCIES exist for MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH in the BRITISH WEST AFRICAN COLONIES.

SALARIES.

Medical Officers receive salaries at the rate of £660 a year, rising by annual increments of £30 to £720 a year, and then on confirmation £720 a year, rising by annual increments of £40 to £960 a year, together with a seniority allowance (payable only in West Africa) at the rate of £72 a year. After three years' service on £960, the salary may be raised to the scale of £1,000 a year, rising by annual increments of £50 to £1,150 a year, together with a seniority allowance at the rate of £100 a year.

Medical Officers of Health receive salary on the above scale beginning at £800 a year, together with seniority allowance of £72 a year. They also draw staff pay at the rate of £150 a year, half of which is payable during leave.

QUARTERS.

Free furnished quarters are provided or an allowance in lieu.

OUTFIT ALLOWANCE.

An outfit allowance of £60 is granted on first appointment.

PASSAGES.

Free first-class passages are provided on first appointment, and when proceeding on or returning from leave.

PENSIONS.

All appointments are pensionable; a minimum service of seven years is required to qualify for a pension. An officer may retire on reaching the age of 50 and may be called upon to retire at the age of 55. Officers of the West African Medical Staff are permitted to retire if they wish with a gratuity of £1,000 or £1,250 after nine or twelve years' approved service respectively, but in that event they receive no pension.

TOURS OF SERVICE AND LEAVE.

A tour of service in West Africa lasts from twelve to eighteen months at the discretion of the Colonial Government, and is followed by leave at the rate of one week for each completed month of residential service. Leave begins on the date of arrival in England.

PROMOTION.

There are good prospects of promotion in the West African Medical Staff.

COURSE OF INSTRUCTION.

Selected candidates are required to attend courses of instruction in tropical medicine and hygiene at either the London School of Hygiene and Tropical Medicine or the Liverpool School of Tropical Medicine or the University of Edinburgh.

Further information regarding the conditions of service, pensions, etc., may be obtained from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, to whom applications should also be addressed.

Royal East Sussex Hospital, HASTINGS.

Applications are invited for the post of PATHOLOGIST to the above Institution (honorarium £200 per annum).

Candidates must be either a Fellow or a Member of the Royal College of Physicians of London, Edinburgh, or Northern Ireland, or be a Graduate in Medicine of one of the Universities of the United Kingdom, and also be duly registered under the Medical Acts.

The successful candidate will be at liberty to practise privately as in the case of the former holder of the post, but must continue to give priority to Hospital and such Public Health Authorities' work as may be arranged for, and the use of the Laboratory for private work is subject to certain conditions.

A trained Laboratory Assistant is provided by the Hospital.

Further details as to the possibilities of the post and practice may be obtained on application.

Applications, accompanied by copies of three recent testimonials, should reach the Secretary not later than 12 noon on Saturday, March 16th.

The post of MEDICAL OFFICER to the V.D. Department under the Public Health V.D. Regulations, 1916, is also vacant, and candidates are eligible to apply for this post, the appointment being subject to the approval of the Ministry of Health and the Local Authorities. This post has been held by the Pathologist, and carries with it a salary of £375 per annum and other emoluments of the minimum value of approximately £50 per annum.

Applications are also invited for the post of [illegible] ANT PHYSICIAN to the [illegible] must be either a Fellow or [illegible] College of Physicians of [illegible] or Northern Ireland, or be a Graduate in Medicine of one of the Universities of the United Kingdom, and also be duly registered under the Medical Acts.

Applications, accompanied by copies of three recent testimonials, should reach the Secretary not later than 12 noon on Saturday, March 16th.

WILFRED G. KEMSLEY, Secretary.

Birkenhead General Hospital. (156 Beds.)

Applications are invited for the post of CASUALTY SURGEON (male). Salary £100, with board and residence; to take up duties about March 25th.

Applications, stating qualifications, experience, and nationality, with three copies of recent testimonials, to be sent to the Secretary-Superintendent by March 12th.

Sec., New Zealand Branch), British Medical Association, P.O. Box 166, Wellington, New Zealand.		

Address: B.M.A. House, Tavistock Square, W.C.1. By Order of the Council of the British Medical Association.
February 27th, 1929. ALFRED COX, Medical Secretary.

St. Peter's Hospital for Stone, ETC.,
Henrietta Street, Covent Garden, W.C.2.

Applications for appointment as HOUSE SURGEON are invited from male candidates with previous experience in a similar office at a General Hospital. The salary offered is at the rate of £75 per annum, with board, lodging, and laundry.

At the expiration of his term of office, which is for six months from April 1st, the House Surgeon, subject to the recommendation of the Medical Staff, is appointed Resident Surgical Officer for a similar period of six months.

Applications, accompanied by copies of testimonials, will be received by the undersigned not later than first post on Wednesday, March 6th.

BEECHEY ROGERS, Secretary.

Royal Manchester Children's HOSPITAL, PENDLEBURY,
Near MANCHESTER. (190 Beds.)

Wanted, a RESIDENT MEDICAL OFFICER and a RESIDENT SURGICAL OFFICER, salary £125 per annum, who will be appointed for six months.

Candidates must be unmarried, doubly qualified, and duly registered. Previous hospital experience essential.

Applications, stating age, and accompanied by copies of not more than three testimonials, to be sent to the undersigned not later than March 6th. Duties to commence April 1st.

Canvassing, directly or indirectly, may disqualify.

By Order,
W. M. HUMPHRY, Secretary.

Royal Manchester Children's HOSPITAL, OUT-PATIENTS' DEPARTMENT, GARTSIDE STREET, MANCHESTER.

Wanted, for the Out-patients' Department, TWO ASSISTANT MEDICAL OFFICERS, non-resident, salary £150 per annum, who will be appointed for six months.

Candidates must be doubly qualified and on the Medical Register. Particulars of the duties can be obtained from the Secretary. The hours of duty are from 9 a.m. till 1 p.m., or until the work of the Dispensary is finished. Patients' attendance number 94,000 per annum. Duties to commence April 1st.

Applications, stating age, and accompanied by copies of not more than three testimonials, to be sent to the undersigned not later than March 6th.

Canvassing, directly or indirectly, may disqualify.

By Order,
W. M. HUMPHRY, Secretary.

Leicester Royal Infirmary.
(400 Beds.)

Vacancies for RESIDENT MEDICAL OFFICERS are expected to arise on April 1st for a HOUSE SURGEON, RESIDENT CASUALTY OFFICER, and HOUSE PHYSICIAN. Salaries at the rate of £125 per annum. Applicants should have held a Resident Hospital post, or had special experience of Hospital work. Election about the middle of March.

Applications to the undersigned by first post on Monday, March 4th.

HARRY JOHNSON,
Feb. 18th, 1929. House Gov. & Sec.

West London Hospital,
Hammersmith Road, W.6 (225 Beds.)

Applications are invited for the post of HONORARY ASSISTANT ANÆSTHETIST. Candidates are required to be registered under the Medical Act, to send applications, with copies of testimonials, so as to reach me not later than Thursday, March 21st; to attend the Medical Council Meeting at 4.30 p.m. on Friday, March 22nd, and prior to that date to call upon and send copies of their applications and testimonials to each member thereof; to abstain from canvassing, but nevertheless to send copies of their applications and testimonials to the Members of the Board of Management, who will elect on Tuesday, March 26th, at 5 p.m., when selected candidates must be in attendance.

H. A. MADGE, Secretary.

The Kensington, Fulham and CHELSEA GENERAL HOSPITAL.

Vacancy occurs on the Honorary Medical Staff for a PHYSICIAN for Diseases of the Skin. Applications are invited from qualified and registered medical gentlemen, engaged solely in the practice of Dermatology. The ... of three ... of the appointment ... signed not ... which is ... have 112 ... one attendance per week in the Out-patients' Department, which is being kept open during the rebuilding.

SUPERINTENDENT,
194, Finborough Road, S.W.10.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LONDON, [illegible] mixed general Practice. Income approxima[illegible] appts. and panel of over 3,000. Surgery fe[illegible] upwards. If unmarried, ingoing Partner could reside with senior; otherwise, suitable house available. Premium 2 years' purchase, half by arrangement.
2. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—A half share, with succession to the whole in about two years, in a very old-established non-panel Practice, held by Vendor 26 years. Steady average income of £2,300. Surgery fees 2/6 and 5/6, visits mainly 5/- and 7/6. Very little midwifery. Good house, in main road, with garden. Held on lease, with nearly 15 years to run, at a rental of only £55 p.a. Premium 2 years' purchase. Very good scope for increase.
3. KENT.—COUNTRY PRACTICE, within six miles of the Coast.—Old-established mixed general Practice. Income for past twelve months £1,672, including appts. about £60, and panel of over 700. Fees 3/6 to 21/-. Not much midwifery 2 to 7 gns. Good house, with 2 reception, 5 bedrooms, etc. Large garden and orchard. Garage for 2 cars. Price for freehold £1,350. Sport of all kinds, and schools within reach. Premium £2,250.
4. PARTNERSHIP.—SOUTH COAST.—In a fashionable watering-place, the two-thirds share is for disposal in a mixed Homœopathic and Allopathic (roughly half and half) good-class non-dispensing, non-panel connection, in which there is a certain amount of surgery, and ingoing partner should be an operating surgeon. Receipts average over £3,600 p.a. Fees 10/6 upwards. Very little midwifery. Large and suitable maisonette available, with ample accommodation, in excellent position. Rent, on lease, £250 p.a. Premium for share 1½ years' purchase.
5. SURGICAL P[illegible]NTY.—Large Hospital Town.—A pu[illegible]endor over 20 years, is for disposa[illegible] Income over £4,600. Consultations [illegible]) to 30 gns. and over. Detached residence, with large accommodation and modern conveniences. Rent, on lease, £250 p.a. Premium 1½ years' purchase. Six months' introduction, or longer if required. A Nursing Home is run, in connection with the Practice, which shows a profit of £1,000 p.a., and which is also for disposal at a moderate price, with the furniture at a valuation. Premises can be rented on lease.
6. PARTNERSHIP.—Within 3 miles North-West of Charing Cross.—The half share of an old-established middle and working-class Practice, averaging about £2,100 p.a., including panel of 1,500. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 bedrooms, bathroom, kitchen, etc. Small garden. Net rental, on lease, about £60 p.a. Premium 2 years' purchase.
7. HAMPSHIRE.—PARTNERSHIP.—Third share of an old-established unopposed Country Practice, in very pretty district within a few miles of a large town, and producing nearly £2,500 p.a., including appointments £130, and panel of 1,520. Visits 5/6 to 21/-. Mids. 2 to 10 gns. Large house (having eight or nine rooms, with garden, etc.), which must be purchased, or ingoing partner could reside in rooms until a smaller one becomes available. Premium 2 years' purchase, half down and balance in 12 or 18 months.
8. [illegible]ntry PRACTICE, situated in very [illegible] miles of the coast. Income for past [illegible] fees 5/6 upwards, visits 5/- to 21/-. [illegible] of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
9. NORTH [illegible]ed general Country PRACTIC[illegible] and offering scope. Average [illegible] Law appt. and panel of 660. Fees 5/6 to 10/6. Good house, on lease, rent £84 p.a. Excellent schools within reach. Premium 1½ years' purchase.
10. HOME [illegible]T.—Old-established mainly [illegible]e for the last year £550, [illegible] 7/6. Little midwifery [illegible] mortgage. Sport of all k[illegible] Premium £850.
11. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share (and up to one-half in two years' time) is offered in an old-established mixed general Practice, averaging about £2,000 p.a., with good scope. Non-panel at present, but ingoing partner should undertake this work. Fees 5/6 to 7/6, a few at 15/-. Little midwifery 3 to 10 gns. Suitable house can be bought. Sport of all kinds. Premium 2 years' purchase.
12. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
13. LONDON, S.E. (CROYDON AREA).—Old-established rapidly increasing middle-class PRACTICE. Income for immediate past year over £1,300, including panel of 700. Surgery fees 2/6 to 5/-. Visits 5/6 to 10/6. Thirty midwifery cases yearly from 3 to 10 guineas. Very commodious house on lease, with 11 years to run, rent £70. Premium £2,000.
14. NORTH [illegible]N.—A one-third share (with increase up [illegible]ery old-established and increasing mixed-clas[illegible] about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
15. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of *Hospital (nearly 300 beds)* and successor will be appointed.
16. NOTTINGHAM.—Good middle-class PRACTICE offering good scope and having small panel which could be largely increased. Gross cash receipts about £400 per annum. Fees 3/6 to 21/-, medicine extra. Very good modern corner house in pleasant residential district. Rent on lease £80 p.a. Premium £750.
17. ESSEX.—SMALL COUNTRY TOWN.—Well-established and increasing PRAC[illegible]ast twelve months £768, including panel [illegible] worth over £60 p.a. Advice and medic[illegible]isits 5/6 to 21/-, medicine extra. Mids. [illegible]as. Exceptionally nice house, with loung[illegible]ooms, and good professional rooms and [illegible]pply, electric light. Large garden, with tennis court. Garage for two cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
18. [illegible]F LARGE TOWN.—Old-established PRACcars. Average income for the past twelve panel of nearly 1,500. Fees 2/6 to 10/-, in its own grounds, and containing 5 reception, 4 bedrooms, dressing room, 3 professional rooms. Central heating. Electric light. Garden, with greenhouse. Garage for 3 cars. Price for leasehold £2,100, of which about £1,500 could remain on mortgage. Premium 1½ years' purchase, part by instalments.
19. LONDON, S.E.—Outlying Suburb.—Very well-estab growing mixed general PRACTICE, situated in pleasant district within easy reach of town. Gross cash receipts for immediate past twelve months nearly £2,650. Panel of about 2,200. Fees 2/6 to 7/6. Midwifery from 3 gns. (about 40 cases yearly). Moderate expenses. Seven-roomed house, with kitchen, 2 waiting rooms, dispensary, and consulting room. Garden. Brick-built garage. Premium £4,500.
20. [illegible] COUNTRY PRACTICE, situated in good [illegible]1 receipts for past 12 months about £1,000 [illegible]00. Advice and medicine from 3/6, visits [illegible]ine extra. Lowest midwifery 2½ gns. Exe, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1½ acres, and 12 acres of grassland. Recently re-decorated throughout. Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
21. CHANNEL ISLANDS.—Old-established general PRACTICE. Present income approximately £700, but large scope. Advice and medicine 5/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.
22. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. Gross cash receipts for immediate past 12 months £657, including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200. Premium 1½ years' purchase.

REQUIRED.—MEDICAL OFFICER for Cable Company. Salary £500 p.a., all found. Three years' engagement. First-class out and home. Must be of British nationality and under 30 years of age. Sail end of March. Personal application preferred.

Full Schedule of Terms and Conditions will be forwarded on application.

Throughout the span

of allotted years — from infancy with restricted diet, through manhood with irregularity of habits, to old age with failing muscular strength and intestinal atony, constipation besets "all types and conditions of men."

The remedy lies not in the doubtful results of harsh cathartics, but in helping the colon back to normal activity.

AGAROL BRAND COMPOUND

The original agar-agar emulsion

is dependable, mild, non-irritating to the organs. It lubricates the intestinal tract, softens the impacted fæces, and reactivates the peristaltic force and action.

A liberal quantity of Agarol Brand Compound for trial sent without cost or obligation to physicians.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar [illegible] with Phenolphthalein

[illegible]ility; [illegible]ficial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Amiodoxyl Benzoate

in Infectious Arthritis

Until now there has never been anything but hopelessness in the treatment of Chronic Arthritis medically. Judging from the clinical work of Young and Youmans (J. A. M. A. September 4th, 1926), Millard Smith (Bos. Med. & Surg. Journal, March 31, 1927) and Norbert C. Trauba (J. A. M. A. Oct. 1, 1927), there is now some hope presented in the form of Amiodoxyl Benzoate, the Ammonium salt of o-iodoxy benzoic acid If only fifty percent of your cases are improved, this drug is worthy of a trial. If it checks the progress of the disease and makes subsequent orthopedic and surgical methods of treatment easier and more effective it has accomplished something. Amiodoxyl Benzoate is administered intravenously in physiologic saline solution (1 gram to 100 c. c.), and is supplied in packages of ten 1-gram vials; also in 50-gram bottles. The usual course of treatment is from six to eight injections, administered twice a week, if conditions permit.

Parke, Davis & Co.

LIVER EXTRACT

In Pernicious Anæmia

THE LIVER EXTRACT offered by Parke, Davis & Co., for use in the treatment of pernicious anæmia, is prepared by a method that has been shown to produce an exceedingly active product. It is supplied in vials each containing the extract from 100 grammes (nearly four ounces) of fresh liver, the contents of three or more vials being taken daily.

The P., D. & Co. Liver Extract is a palatable preparation with a pleasant salty taste, and it may be taken sprinkled over potatoes, meat or bread. Its miscibility with water, milk, soup, orange or lemon juice and other liquid foods also suggests other acceptable modes of administration.

Supplied in packages of 24 vials.

Further details will be furnished on request.

"PITIBULIN"
TRADE MARK

Denotes
Unvarying Pituitary Extract

Conforming to the requirements of the Therapeutic Substances Regulations, 1927, "Pitibulin" is prepared according to the official standards, its activity being now expressed in terms of the accepted unit.

As heretofore, "Pitibulin" maintains the stringently high criteria of therapeutic efficiency, safety in use and stability, self-imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians.

Preparations :

"Pitibulin" Obstetric (5 units per c.c.) (½ and 1 c.c. in boxes of 6 and 12 ampoules)

"Pitibulin" Surgical (10 units per c.c.) (½ and 1 c.c. in boxes of 6 and 12 ampoules)

Literature giving fuller particulars of the therapeutic application of "Pitibulin" will be sent on request.

Which Type?

PREBLE points out that "of all the diseases which may be classified as typical, none is truer to its type than the pneumococcus pneumonia". The treatment of pneumonia, *whatever the type*, is essentially symptomatic. And symptomatic therapy is *necessary* in pneumonia, first, because it is not always possible to combat the *cause* of the disease effectively, and, second, because it is necessary to correct functional faults and to stimulate functional deficiency, both of which determine the course of the infectious process to a large extent.

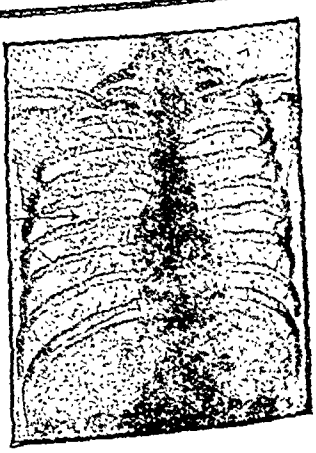
Applied as a jacket over the entire thoracic wall, Antiphlogistine will serve to allay the painful pneumonic process, facilitate expectoration and ease the efforts of coughing. By virtue of its marked decongesting action, it sustains the vasomotors and the circulation, decreases toxemia and, being thermogenetic, assures a maximum of comfort with a minimum of disturbance to the suffering patient.

Whatever the type—

Antiphlogistine

is indicated.

Every physician should have a copy of our brochure "The Pneumonic Lung" (illustrated in color), epitomizing the etiology, pathology and symptomatology (including roentgenographic chest plates) of the various types of pneumonia. Please use the form below for your free copy.



THE DENVER CHEMICAL MFG. CO.,
LONDON, E.3.

You may send me, free of all charges, your illustrated brochure, "The Pneumonic Lung," together with sample of Antiphlogistine for clinical trial.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

SAUNDERS' New Books

In Three Volumes — *Just Issued*

BLUMER'S BEDSIDE DIAGNOSIS

Edited by GEORGE BLUMER, M.D., David P. Smith Clinical Professor of Medicine, Yale University Medical School. Three octavo volumes, totalling 2,820 pages, with 890 illustrations. Per set, Cloth, £6 15s. net. Index volume free.

"... the book is well bound, the print is excellent, and the illustrations carefully chosen and well reproduced. Not only is each volume indexed but a separately bound index to the whole three volumes is provided, so that fruitless searching in the wrong volume can be avoided. The physician will find it hard to get a finer book."—THE LANCET.

New (3rd) Edition — *New (3rd) Edition*

NEOPLASTIC DISEASES

By JAMES EWING, Sc.D., M.D., Professor of Pathology, Cornell University Medical School. Octavo of 1,127 pages, with 546 illustrations. Cloth, 63s. net.

"It would be strange to come across any pathological laboratory where this book did not show the signs of frequent consultation. To the surgeon it is a necessity if he would seek to be more than a mere operator. The specialist and the practitioner will find it a mine of useful information."—BRITISH MEDICAL JOURNAL.

Just Issued — *New (2nd) Edition*

EXAMINATION OF PATIENTS

By NELLIS B. FOSTER, M.D., Associate Professor of Medicine, Cornell University College of Medicine. Octavo of 392 pages, with 83 illustrations, a number in colours. Cloth, 21s. net.

"Dr. Foster here records his routine in the examination of patients, and the precision of his writing, the thoroughness of his method, and his critical but sympathetic attitude to recent advances make his book a most valuable one to all those engaged in general practice."—THE LANCET.

A New Work — *Just Issued*

GONORRHŒA IN THE MALE

By P. S. PELOUZE, M.D., Associate in Urology and Assistant Genito-Urinary Surgeon, University of Pennsylvania. Octavo of 351 pages, illustrated. Cloth, 24s. net.

"The keynote of this book is simplicity—simplicity in exposition and simplicity in treatment. ... Dr. Pelouze's book should be read by every practitioner who intends to treat gonorrhœa."—BRITISH MEDICAL JOURNAL.

Just Issued — *New (9th) Edition*

GENERAL BACTERIOLOGY

By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology in the University of Chicago, and in Rush Medical College. Octavo of 778 pages, fully illustrated. Cloth, 28s. net.

"One of the best balanced and most scholarly of the current textbooks upon bacteriology, and has the additional charm of viewing the subject widely, not being slavishly devoted to the pathogenic micro-organisms to the exclusion of due consideration of other forms."
THE LANCET.

Just Issued — *New (5th) Edition*

PRINCIPLES & PRACTICE OF OBSTETRICS

By JOSEPH B. DE LEE, A.M., M.D., Professor of Obstetrics at the Northwestern University Medical School, Chicago. Large octavo, 1,149 pages, with 1,128 illustrations on 923 figures, 201 of them in colours. Cloth, 55s. net.

"The author may be again congratulated on what is truly a monumental work. The term textbook is inadequate, encyclopædia would be a more apt description."—BRITISH MEDICAL JOURNAL.

A New Work — *Just Issued*

LOCAL ANÆSTHESIA

By GEZA DE TAKATS, M.D., M.S., Assistant Professor of Surgery, Northwestern University Medical School, Chicago. Octavo of 225 pages, 117 illustrations. Cloth, 18s. net.

"Can be recommended as a concise reliable guide to those inexperienced in this method of anæsthesia."—
BRITISH JOURNAL OF SURGERY.

Just Issued — *Just Issued*

NUTRITION AND DIET

By JAMES McLESTER, M.D., Professor of Medicine at the University of Alabama. Octavo of 753 pages. Cloth, 36s. net.

"The book is characterized by a sane and well-balanced outlook and a comprehensive and succinct treatment of the several aspects of dietetics."—BRITISH MEDICAL JOURNAL.

THE
SCIENCE of LIFE

An original work which sheds new light on problems of the utmost interest to every intelligent man and woman.

By **JULIAN HUXLEY**
H. G. WELLS & G. P. WELLS

THIS original new work appeals first and foremost to readers of sound general education who wish to bring their minds up to date with current biological knowledge. It is lucid, persuasive, complete and exact, and fully and abundantly illustrated; every section is alive with fresh and stimulating ideas. It is the joint work of three able and original men, of whom two are biological scholars and investigators, and the third one of our most brilliant thinkers and writers. It tells all the main facts and all the newest concepts and discoveries about our bodies and our minds in health and disease. It gives a fascinating survey of the whole realm of natural history. It relates the history and adventure of life in time. It sets before its readers with perfect fairness and clearness the essentials of the great controversies about Evolution and the present state of that discussion. It enters into the issues of what are called "supernormal" phenomena. It is, in fact, an encyclopedia of biology and biological fact.

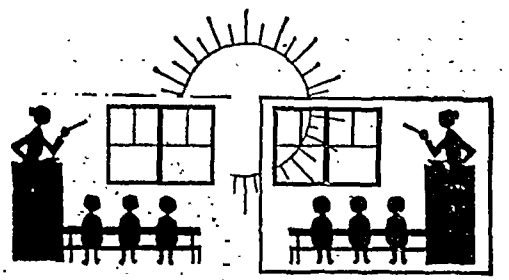
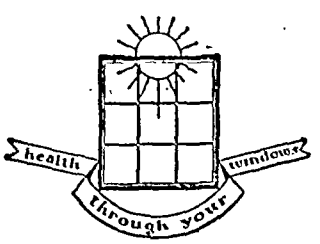
Indoor Sunshine for Delicate Children



THE notable results which have been obtained by "Vita" Glass in schools suggest that this new window glass will be useful to medical men in the treatment of delicate children. "Vita" Glass brings indoors the biological and therapeutic wavelengths of the ultra-violet rays which are shut out by ordinary window glass. Authoritative evidence is available showing the beneficial effects of this gentle, sheltered heliotherapy on growing children. Wherever the weakly child is kept indoors for long periods owing to inclement weather, "Vita" Glass can be of value in providing an approximation of outdoor conditions.

"Vita" Glass is the product of British science and British industry. It has recently been reduced in price to bring it within reach of a wider public, and medical men may safely prescribe it for patients of only moderate means.

Those interested in "Vita" Glass for their own homes or for their patients are invited to send for full information concerning its use in Hospitals, Sanatoria, Schools, Offices, Factories and private houses. Write to "Vita" Glass Marketing Board, 9, Aldwych House, London, W.C.2.



"VITA" GLASS

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

V69 *"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.*

ULTRA-VIOLET IRRADIATION—

by

The 'SCHEIDT' PROCESS

in which COLD QUARTZ TUBES with remarkable U.V. spectra give an easily controlled and positive activation, and leave the products

UNCHANGED in TASTE or ODOUR

THE ONLY PROCESS OF EFFECTIVELY IRRADIATING MILK WITHOUT TAINT OF OZONE AND CARBON DIOXIDE.

THE value of irradiated milk for rachitic children, and in cases of tuberculosis of the bones, has been shown many times. (See *British Medical Journal*, March 28th, 1925; *The Lancet*, January 2nd and December 25th, 1926; *The British Journal of Radiology*, February, 1926; and *The Journal of Actinotherapy*, June, 1928). But hitherto the process of irradiation has always tainted the final product.

This difficulty has now been definitely overcome!

THE 'Scheidt' Apparatus for cold tube activation is now installed, and in process of installation, at many of England's leading Clean Milk Farms and Dairies. These Farmers understand Milk and how it should taste where Infant Nurture is in question.

They have adopted the 'SCHEIDT' PROCESS!

Clinical, X-ray, and Blood Tests, carried out by eminent medical men using *only the Scheidt Cold Tube apparatus* (as against Quartz Lamp), are available, and have been quoted in the literature of Foreign Competitors, who appear to have thus paid an unconscious tribute to the value of the 'Scheidt' process.

MEMBERS OF THE MEDICAL PROFESSION ARE INVITED TO A DEMONSTRATION AT

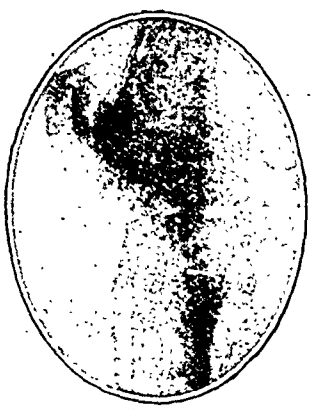
'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated.
Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Radiograph of Hip-joint in Rheumatoid Arthritis

Prescribed in numerous cases *of nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

TRUFOOD LTD., THE CREAMERIES, WRENBURY, NR. NANTWICH, CHESHIRE.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Therapeutic Ointments

Ung. Renaglandin and Ung. Renaglandin Anaesthetic . . Invaluable in Hæmorrhoids—Styptic.

Ozoline . . . An ideal method of employing the detergent action of Hydrogen Peroxide.

Kalzana promotes Calcium Retention

The value of Kalzana tablets lies in their combination of calcium lactate and sodium lactate. In the body the sodium lactate becomes converted into sodium carbonate and imparts the requisite alkalescence to the blood which is necessary to ensure calcium retention. The reports of eminent physicians show that Kalzana possesses all the advantages which one may expect from a calcium preparation.

"The Practitioner" says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

calcium sodium-lactate

(Made by A. WULFING & CO., Amsterdam, Holland.)

Also supplied *direct* for Doctor's own dispensing at 15/- per 1000 plain tablets.

Samples for the medical profession on request to:
THERAPEUTIC PRODUCTS LTD. (Dept. B.M.51), Napier House, High Holborn, London, W.C.1.

OVALTINE

FOR INSOMNIA.

Sleeplessness is a common feature of Neurasthenia. The value of "Ovaltine" in this condition is exceptional. A cup of "Ovaltine" taken upon retiring allays nervous irritability, and the patient passes into a natural and healthful sleep.

As evidence of the value of "Ovaltine" in Insomnia the following extracts from unsolicited medical reports are noteworthy:

"The patient slept the first night I used 'Ovaltine,' but I thought it merely a coincidence. By continuing its use, however, I am convinced of the value of 'Ovaltine' to induce sleep."

"In a case of Neurasthenia associated with sleeplessness and difficult feeding I gave my patient 'Ovaltine.' To my great satisfaction 'Ovaltine' was retained without difficulty, and rapid improvement followed."

"Ovaltine" is a rich concentration of the vitalizing principles of malt, milk, and eggs. Its delicious flavour and its high nutritive and digestive qualities render it a food beverage of outstanding worth.

A liberal supply for clinical trial sent free on request.

CAPROKOL

(Hexyl-resorcinol B.D.H.)

Caprokol gives immediate symptomatic relief in infections of the urinary tract; this is appreciated by physician and patient alike.

Caprokol treatment ensures hours of continuous sleep (unbroken by the necessity for frequent micturition), cessation of pain, and subsidence of fever. The patient's appetite increases, and, as the suffering decreases, the general health rapidly improves.

The final result of Caprokol therapy, in practically every case, is the complete disinfection of the urinary tract and restoration to normal health.

Manufactured and issued in Great Britain by Boots

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

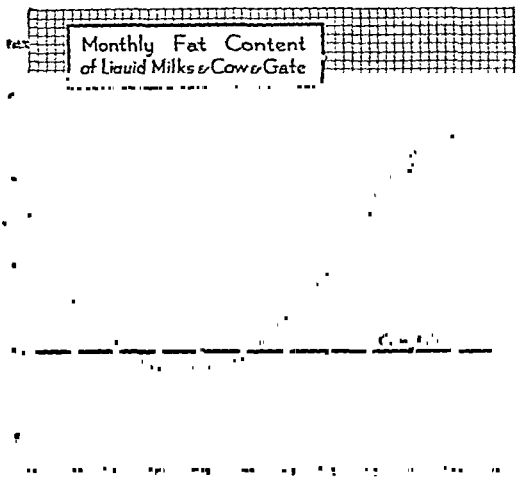
We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

DINNEFORD and Co. LTD.

A RELIABLE BASIS



The above shart shows the large fluctuations in the fat content of liquid milks throughout the year, as compared with the unvarying fat content of COW & GATE, which is based on the fat content of average healthy Breast Milk.

Fat content in COW & GATE reconstituted (1 in 8) 3.4%

Fat content in average Breast Milk 3.3% — 3.5%

This is ONE of the many reasons why COW & GATE is one of the safest and most reliable alternatives when breast-feeding fails, and why it affords the most reliable basis for Infant-feeding modifications.

Cow & Gate Milk Food

Absorbs Intestinal Toxins

Over thirty-six separate poisons have been found in the intestinal tract in cases of alimentary toxemia. These consist of bile acids and alkaline wastes secreted by the intestinal mucous membrane, in addition to a variety of bacterial ptomaines and toxins.

Nujol is a highly active solvent. If it be shaken with a watery solution of indol, more than half the indol is quickly taken up. *Nujol readily dissolves these waste and* poisonous substances, many of which are more soluble in liquid petrolatum than in water.

Thus Nujol, which is not absorbable, takes up a very considerable portion of toxins found present in the intestinal tract and prevents their absorption into the body. The brownish colour of Nujol as seen in the stool is due to the substances which it holds in solution.

Laxatives which liquefy the intestinal contents and provoke anti-peristalsis, frequently increase the absorption of intestinal toxins. Nujol not only dissolves and removes intestinal toxins, some of which are highly active poisons even in minute quantities, but also by speeding up the intestinal rate of flow it prevents their formation. Effective in all types of constipation.

Aesculapius

CARDIO-VASCULAR ATONY:

Post-pituitary extract exerts specific effects on the musculature of the cardio-vascular system, increasing tone and thereby raising arterial tension. It is a valuable adjunct in dealing with syncope, extreme exhaustion, and shock. Excellent results are obtained with it in the treatment of pneumonia.

INFUNDIBULIN

An Extract of the Posterior Lobe of the Pituitary Gland standardised so that 1 c.c. contains 10 International units. In addition to the uses described above, its value in the practice of Midwifery is indisputable. It is available in 1 c.c. and 0.5 c.c. ampoules.

Prepared at Evans' Biological Institute, Runcorn.

Regesan

CREAM OF MAGNESIA WITH LIQUID PARAFFIN

(Contains 30% of Regelax Liquid Paraffin)

An excellent combination of two proven remedies—exhibiting the advantages of both and minimising the tendency of Liquid Paraffin to leak. It is an emulsion, free from oily taste, in which the Liquid Paraffin is held in a very finely divided state, and as such is suitable for the treatment of Constipation, with which digestive troubles are associated.
Regesan Cream of Magnesia with Liquid Paraffin forms a soft, easily evacuated faecal mass, and is particularly useful in the treatment of Hæmorrhoids.

For Head Colds Prescribe "Mistol"

MISTOL and the Mistol Dropper are a real advance in nose and throat therapy. Menthol, eucalyptol, and camphor are combined in a specially prepared petroleum base, which keeps these soothing and healing ingredients in direct contact with the mucous membrane for a considerable length of time.

Unlike douches, Mistol avoids any possibility of sinus trouble. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Sold in original sealed cartons containing a—

Local Anæsthesia in Surgical Practice

MAXILLARY SINUSITIS.

Typical Case.

L. M., female, aged 24 years.

Diagnosis: Right maxillary sinusitis.

Operation: Denker's operation with drainage.

Anæsthesia: Maxillary nerve block with 22 c.c. of 1 per cent. Novocain-Adrenaline.

Operation: The needle was introduced at a point of 2 cm. posterior to the external canthus of the eye just below the zygoma. Paraesthesia was felt in the right side of the face, and 2 c.c. of a 2 per cent. Novocain-Adrenaline solution were injected. Within a minute the towel pins could be placed upon the lip. The lip was retracted and the sinus opened, curretted, and drained without the production of pain.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

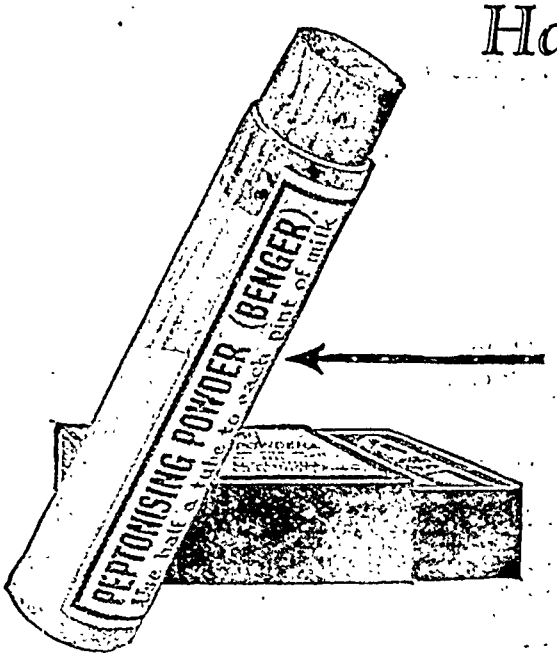
The most efficient Peptonising Powders!

Half a tube of Benger's is enough!



While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1—Box of 6, 1/-; No. 2—Box of 12, 1/8

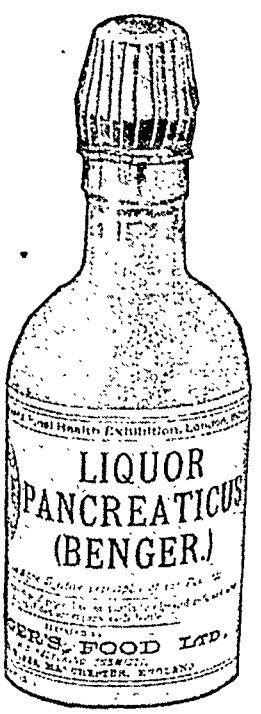
Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.

Prices: 3/-, 5/6 and 10/6



Medical men may obtain full particulars of Benger's preparations post free on request.

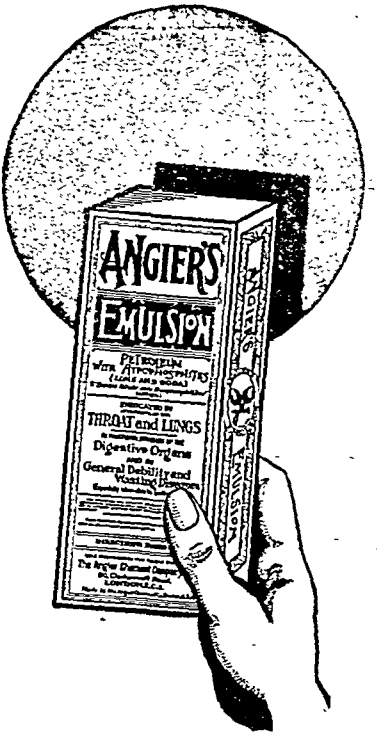
BENGER'S Food

In Convalescence

after Influenza, Pleurisy, Pneumonia, Bronchitis.



The soothing, inflammation-allaying properties of Angier's Emulsion and its general tonic effects especially commend its use in convalescence from acute respiratory affections. It will clear up any remaining catarrh, whether of the respiratory or digestive organs. It will restore tone to the digestive functions, and greatly improve assimilation and nutrition.

An absolutely perfect emulsion, it is presented in a form pleasing to the taste, and acceptable to the most fastidious. Moreover, it can be administered to advantage in conjunction with other remedies, such as salol, aspirin, bismuth, etc.

Angier's Emulsion is made with petroleum specially purified for internal use. It is the original petroleum emulsion — the result of many years of careful research and experiment.

PUBLIC NOTICE

re

"RYVITA CRISPBREAD"

and

"THE RYVITA CRISPBREAD HABIT"

We acknowledge with much pleasure and grateful thanks the volume of congratulations on our successful introduction of "Ryvita Crispbread" to the British Isles.

When we gave to the British public this new and invaluable food—creating throughout our country the *Ryvita Crispbread habit*—we started what has now become almost a revolution in the bread-eating habit of the nation.

"Ryvita Crispbread" is the successful outcome of generations of experience directed to making just this one thing *right*.

That it is, and does, all that we claim for it is proved by the welcome it has received from Doctors, Dentists, and food experts, who not only prescribe it but have it as the daily bread in their own homes.

Because of its success, not only with the professions and the experts, but with the ordinary folk of these islands, there have arisen a number of "imitation Crispbreads." Some of these are not bad—*as imitations*—some are bad, some quite bad.

We make "Ryvita Crispbread" in Sweden because this type of bread is essentially and characteristically Swedish. The special ovens which we use are a mere item compared with the skill and long experience needed to make Ryvita *right*. It has taken generations of experience devoted exclusively to making just this type of bread to win the present perfection of "Ryvita Crispbread."

Although we make "Ryvita Crispbread" in Sweden, we who own and control the Ryvita Company are British. We buy British when it is best. But, like most other British people, we *will* have the best.

When we smoke a cigar it must be—Havana made in Cuba. After dinner, when we offer our friends a glass of port—it must be port from Portugal. When we have a little party, our champagne must be genuine from France. The suggestion that you should buy *imitation* Crispbreads merely because they are "British made" is as ludicrous as it would be to claim pre-eminence for British Cigars—British Port—or British Champagne.

Whilst the Ryvita Company is proud of its achievement in popularising the healthful *Ryvita Crispbread habit* in this country, it entirely dissociates itself from these hastily prepared substitutes.

The genuine original "Ryvita Crispbread"—crisp, scrunchy, and delicious . . . . the bread of life and health—helps to make indigestion, constipation, malnutrition, and obesity unknown.

"Ryvita Crispbread" is sold by all good grocers and stores at 1/6 per 40-50 slice (1 lb.) carton; ½ lb. carton, 10d.

THE RYVITA COMPANY

96, SOUTHWARK STREET
LONDON, S.E.1

★ FREE—*A postcard sent to-day will bring you by return a generous free sample of the genuine original "Ryvita Crispbread"*

"RYVITA CRISPBREAD MAKES YOU FIT—AND KEEPS YOU SLIM"

It is now established that lack of vitamins is responsible for a considerable percentage of the total disease in the world; consequently it is of great importance for the physician to know of a thoroughly reliable preparation containing, in accurately-standardised quantities, all three Vitamins—A, B and D.

Such a preparation is Radio-Malt.

Radio-Malt is of special value as an anti-infective, as a corrective of faulty calcium and phosphorus metabolism, as a galactagogue, and for its anti-rachitic and antineuritic properties.

Radio-Malt possesses also remarkable power to stimulate appetite and to rebuild wasted tissue; it is of great value, therefore, as a tonic for convalescents of all ages.

EXAMPLE OF CLAY FIGURES, THE ADOPTION OF WHICH IN PLACE OF HUMAN IMMOLATION WAS DECREED BY SUININ, ONE OF THE PIONEER EMPERORS OF JAPAN.—The decree ran: "Henceforth these clay images must be set up at tumuli; let not men be harmed." This was aimed against the custom of burying alive retainers (and horses) at the sepulchre of a prince to serve him in the next world. The circumstances in which it was issued are thus recorded in the Annals relating to Suinin: "28th year, Winter, 10th month, fifth day. Yamato-kiko-no-Mikoto, the Emperor's younger brother by the mother's side, died . . . . Thereupon his personal attendants were assembled and were all buried alive upright round his sepulchre For many days they died not, but day and night wept and cried. At last they died and rotted. Dogs and crows assembled and ate them. The Emperor, *hearing the sound of their weeping, felt saddened and pained in his heart. He commanded* all his high officers, saying: 'From now and henceforth, plan so as to stop causing men to follow the dead.'" The name of one of the Emperor's counsellors, Nomi-no-Sukuné, should be associated with the humane decree which followed, for it was he who suggested the substitution of clay images. Custom, however, was too strong and the practice of human immolation was kept up in some degree until about A.D. 700.

CONSTIPATION IN ACUTE ILLNESS

IN fevers, and such acute inflammatory conditions as pneumonia, constipation is nearly always present —adding much to the patient's discomfort and often seriously hindering recovery. The necessity for avoiding the slightest additional irritation of the morbidly hypersensitive mucous membrane bars out the use of most of the customary purgative pills and mixtures.

In such circumstances, Eno's "Fruit Salt" proves it self the Aperient of Preference. Acting, as it does, solely through its power of retaining in the intestinal canal the water drunk with it or shortly afterwards, it stimulates peristalsis in the way of Nature—without pain, irritation, or nausea. Another advantage of Eno which may rightly be stressed is that it **contains no trace of the mineral purgative salts Sodium Sulphate and Sulphate of Magnesia.**

"The Doctor's Emergency Reminder."

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "THE DOCTOR'S EMERGENCY REMINDER" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

J. C. ENO LTD., 160, PICCADILLY, LONDON, W.1

THE PRESENT POSITION OF LEAD THERAPY IN MALIGNANT DISEASE.*

BY

W. BLAIR BELL, B.S., M.D.LOND., HON. F.A.C.S.,

PROFESSOR OF GYNAECOLOGY AND OBSTETRICS IN THE UNIVERSITY OF LIVERPOOL; GYNAECOLOGICAL AND OBSTETRICAL SURGEON, ROYAL INFIRMARY, LIVERPOOL; DIRECTOR, LIVERPOOL MEDICAL RESEARCH ORGANIZATION.

INTRODUCTION.

At the outset it is advisable once more to express the conviction that by prevention only shall we stay the onward march of cancer. Elsewhere[5] we have dealt with this aspect of the problem, and have indicated that success in this sphere can be accomplished only if we take into account the numerous sources of, and factors concerned in, the irritation of the human tissues that may result in the precancerous state. On the other hand, the alleviation and cure of cancer, once the disease has developed, appears *not to be related to the etiology as such, but rather to the* nature of the cancerous process to be arrested by all the remedial measures at our disposal. Until recently these measures have consisted almost entirely of surgical and radiological procedures, and no impression seems to have been made on the rate of increase in the mortality rate. Clearly, the mortality figures must have been reduced in direct proportion to the number of cases saved, but these have been too few in number to counterbalance the increased incidence rate of the disease, which appears in a great measure to be due to the prolongation of life in civilized communities.

In our opinion the saving of more patients stricken with the disease—often men and women in the heyday of their mental attainments and of their value to mankind—will ultimately come through chemotherapeutical or biochemotherapeutical methods. In regard to the latter, immunifacient and cytotoxic effects by means of specific biological substances were first attempted by us twenty years ago, and are still under consideration. The local treatment of malignant affections has almost, if not quite, reached standardization.

CHEMOTHERAPY IN CANCER.

Successful chemotherapy is particularly difficult even in connexion with the destruction of parasitic organisms that have gained entrance to the body, but in this direction great advances have been made during recent years. When, however, we attempt the elimination by synthetic products of certain cells developed from, and dependent on, ordinary somatic tissues—"organochemotherapy," as it is called—we are faced by many grave difficulties, and we shall probably be held up in our search for substances with a high organochemotherapeutical index until further investigations have been made concerning the functions of the reticulo-endothelial system, and in regard to the physicochemical conditions in which drugs exert their actions on living tissues. Research work along these lines is in its infancy, but nevertheless must be properly appreciated without delay.

The reasons why we adopted the metal lead as our primary constituent for the chemotherapeutical treatment of cancer have so often been stated that no further explanation is necessary.† A point of importance associated with our work is that the encouragement received from the use of crude products has been sufficient to urge us forward to seek improvements especially in the direction of organic complexes containing lead, and, in a general way, hope of ultimate success in the treatment of malignant disease by chemotherapeutical measures has been kindled in others. It is our earnest desire to foster this hope in order that many more labourers may enter this promising field. Interest can best be promoted if we recall a few only of the encouraging developments we have witnessed during our work, and attempt to discover why we have been rewarded with a certain measure of success in the cases now described, some of which have been recorded on previous occasions.

COMBINED TREATMENT OF CANCER.

We have mentioned the utilization of all the remedial agents at our disposal in the treatment of cancer, and it is certain that no doctor, no one with humanitarian instincts, would do otherwise than place the safety and cure of his patients foremost in his mind. It will be seen, then, that not all of our patients have been treated by lead alone. Whenever practicable, we have felt it desirable to assist this treatment by the removal of as much of the growth as possible, the subsequent treatment with lead being commenced immediately. In many cases, too, we have utilized our knowledge of the augmented effect of x rays and radium acting in conjunction with lead, and of the fact that this combination may enable us to obtain satisfactory results with smaller doses of each than would be effective if either were employed alone. This, no doubt, may be open to the criticism that in those cases in which combined treatment has been practised it is impossible to say which agent has produced the beneficial result, when this has been obtained. But, even though we do regard the dictates of humanity, surely we have ample evidence in favour of the use of lead, for in a number of cases in which some preparation of this metal has alone been used recovery has followed. So, too, we now have the knowledge, not only as the result of our own observations, but also of those of Carter Wood,[10] Mottram,[7] and others,[6 8] that while x rays, radium, and lead may each produce a beneficial effect when used separately, an aggregate effect is secured when lead and x rays or lead and radium are applied within a short time of one another.

It will be found, therefore, that some of our cases were treated by lead alone, others by operation followed by lead, and again others by lead and x rays or radium.

INDICATIONS AND CONTRAINDICATIONS FOR TREATMENT WITH LEAD.

We have emphasized the fact that in respect of our present practice the general condition of the patient is of paramount importance. With increased experience we have come to regard the situation of the malignant neoplasm as of lesser importance, and to-day we certainly should neither exclude cancer of the lung nor malignant disease of the central nervous system.

The question of malignant disease of the liver and of a kidney is, however, more difficult, for in the general examination of the patient we lay considerable stress on the integrity of the functions of these organs. It will readily be appreciated that if either be already affected with malignant disease, or be otherwise previously damaged, there is a greatly increased risk of adding to their functional distress by the administration of lead. At any rate in such circumstances great caution is required.

It may be interesting to recall one case (248) in which there was carcinoma of the left kidney. Careful examination revealed the fact that the right kidney was absent. To have treated a patient with lead in these circumstances would have been to court disaster.

Apart from lesions in these two organs, we must also take into consideration the state of the heart and blood. Severe myocardial insufficiency necessitates the most cautious use of lead, and serious anaemia with a low red-cell count precludes the use of this substance until considerable improvement by blood transfusion or other measures has been effected. In the last place, we must also take into careful account the general condition of the patient in regard to acidosis with ketonuria and other constitutional states.

In malignant disease the progress to a fatal issue varies in different patients in a remarkable manner. In some—usually the young—the course is so rapid that the general condition of the patient appears to be little affected until the very end. In others—for the most part the aged—the disease progresses very slowly and appears to produce

* A post-graduate lecture, with lantern illustrations, delivered under the auspices of the British Empire Cancer Campaign and the Leeds and West Riding Medico-Chirurgical Society, in the Medical School, Leeds, on January 9th, 1929. This investigation was undertaken on behalf of the Liverpool Medical Research Organization.

† The chief matters of interest in this connexion were demonstrated.

no serious constitutional disturbance for a very long time. In most patients, however, the malignant process advances at a steady rate, undermining the constitution of the patient, however strong he may previously have been, and sapping his vitality, until what we describe as a condition of profound cachexia supervenes. Now it is in the presence of a state of definite cachexia that we must hold our hand. So long as the patient is in good condition, with a prospect of about six months of life, if other things are equal, treatment may be contemplated. In this matter considerable judgement and prognostic acumen are necessary.

METHODS OF TREATMENT WITH LEAD.

Dosage.—In a general way it may be said that we have tended gradually to decrease the individual doses, while aiming steadfastly at the administration of a high total quantity of lead—that is, 0.5 gram to 0.8 gram or a little more. In a number of cases we have been successful with a smaller total quantity than 0.5 gram of lead, which we believe to be the minimum amount desirable in ordinary circumstances. On the other hand, we have given nearly 1 gram of lead before obtaining a satisfactory final result. Empiricism in this matter is quite impossible; the greatest consideration and care are required if safety to the patient is to be ensured, and a successful result obtained.

Material.—For almost the entire part we have employed a suspension of metallic lead prepared by Professor Lewis and his associates, and the colloidal preparation of lead phosphate made by Professor Heilbron and those working with him. For a time we used a suspension of lead selenide, but this appeared to be almost too stable to give good results, although it is not inert; it is, however, singularly atoxic. Lead-selenium has, however, been successfully employed by Dr. Todd of Bristol,* who was the first to make and use this preparation of lead.

Administration.—Injection of the material into a vein in the arm has been by far the most common method of administration. We have, however, in a few cases, injected the preparation into an artery. Two cases of malignant disease in limbs will be mentioned in which this procedure has been practised, apparently, and so far, with promising results. We look forward to the obvious advantages and possibilities of this route in the treatment of malignant disease of the limbs, mouth, and other regions with a readily available and convenient arterial supply. In a few of our earlier cases intramuscular injections were employed. Ionization with lead of malignant ulcers is, too, a mode of attack which we have practised. We have already referred to the beneficial results that may be obtained by the application of x rays or radium at an interval of four days following the administration of lead.

Mobilization.—We apply this term to the process of bringing the lead that is stored in the body again into the circulation, from which it may be taken up by the growth, if this still be present, or excreted. Some years ago we were faced with the difficulty that in certain patients, who had received what we considered the maximum quantity of lead that could be given with safety, the neoplasm was still in existence or had recurred. It occurred to us to mobilize the lead still remaining in the body by the administration of acids or other chemical substances; and we found this possible. Sometimes stippled erythrocytes reappeared in the blood, and excretion by the urine and faeces was increased. We have, however, no direct evidence that the growth takes up the lead in these circumstances. We are at present inclined to think that the metal already attached to the tumour may be released; and in some cases (for example, patient 185 quoted below) the growth which has not entirely disappeared but is arrested may thereby be released from control and start afresh to develop. Consequently, we now hold the view that so long as any growth remains mobilization must not be practised. Indeed, this procedure should be reserved for those cases in which there has been no sign of neoplastic development for several years, and in which it is desirable that the liver and kidney functions should be normal, as in patient 77 recorded below.

There is no doubt that lead tends to be eliminated from the body in the course of time, and this itself may be a source of anxiety in respect of the possibility of recurrence. It appears most profitable to maintain a supply of lead in the tissues until all danger of recurrence is long past, for we have observed that in such circumstances the placenta in pregnancy several years subsequently (see patients 77 and R. I. 39 described below), and therefore probably a neoplasm, is capable of taking to itself lead from that stored as the result of previous treatment.

GENERAL CHARACTER OF RESULTS.

One of the difficulties that have arisen in the general appraisement of results has been due to the different methods of tabulation adopted by various authors. Those unable to appreciate evidential values have taken the definite stand of "all or nothing"—that is, absolute cures or failures alone, in their view, are worth recording. Moreover, the primary condition attaching to all forms of scientific treatment—namely, that the method adopted shall be properly applied—has not infrequently been ignored. In this connexion it will be found that where a series of failures has been recorded the patients have been so ill that treatment could not be completed, or that the treatment was so conducted that the patients died as the result of it. Such groups of cases should be excluded from any estimation of the effect of treatment—they have no evidential value at all.

Again, it cannot be too forcefully reiterated that in the early application of any new method, however important an absolutely curative effect may be, *arrest and alleviation of the disease must equally be taken into account*, for such phenomena afford a valuable indication of the correctness of the principle of the treatment adopted, and give promise of the fruits of complete victory if the pursuit be pressed.

There is another phenomenon of great interest that has been observed by ourselves and others, concerning which we shall have more to say directly. We refer to the complete arrest or even disappearance of the growth with reappearance after a short or a considerable length of time. From this we may provisionally conclude that it is advisable to continue in a modified form the treatment over a longer period of time than previously considered necessary.

Finally, it may be suggested that in all cases in which a beneficial effect is obtained, the restoration of the natural vital processes plays a part in the result.

CERTAIN CASES TREATED WITH LEAD.*

The number of cases described under this heading are arbitrarily limited by space only, and they are merely representative of the results that may be expected if the work be properly conducted. In two or three cases we have had to accept the statement of the surgeon concerned as to the nature of the primary neoplasm; consequently we think that the interests of truth will best be served if we record the names of those connected with all the cases presented.

(A) *Cases in which the Primary Growth was Treated with Lead alone.*

In this group are included some cases in which the abdomen was opened to secure specimens of growth for histological examination, or the immediate relief of symptoms and physical states, such as intestinal obstruction.

1.—Female, aged 36; married; 3-para.
Diagnosis.—Carcinoma of left breast (section +) with glands in axilla. Pronounced inoperable by Professor R. E. Kelly and Mr. Frank Jeans.
Treatment.—Intravenous injections of partly colloidal lead iodide commenced on November 9th, 1920. Total quantity administered approximately 0.3 gram Pb. Severe reaction.
Subsequent History.—Now alive and well more than eight years later. Two more children; both suckled at previously diseased breast.

77.—Female, aged 27; married; 5-para.
Diagnosis.—Sarcoma small intestine (section +).
Treatment.—Intestinal anastomosis for obstruction by Professor Kelly. Growth irremovable. Intravenous injections of partly colloidal lead iodide commenced February 26th, 1923. Total quantity administered 0.45 gram Pb. Very slight reaction.

* In our forthcoming work on *Some Aspects of the Cancer Problem*, to be published by Messrs. Baillière, Tindall and Cox in the spring or early summer, the cases, here recorded very briefly, are given in more detail and are illustrated. Moreover, *in this book* there will be additional case records and tables, now omitted owing to exigencies of space.

Subsequent History.—Growth disappeared and, so far as original disease was concerned, patient remained well for over five years. Unfortunately she died of toxaemia of pregnancy in May, 1928.

112.—Female, aged 59; married; 2-para.
Diagnosis.—Carcinoma of liver and peritoneum (section +).
Treatment.—Paracentesis twice under the care of Professor John Hay. Exploratory laparotomy. Intravenous injections of partly colloidal lead iodide commenced August 3rd, 1923. Total quantity administered 0.345 gram Pb. No reaction.
Subsequent History.—The patient now alive and well five and a half years later.

185.—Female, aged 27; unmarried; medical student.
Diagnosis.—Retroperitoneal sarcoma (section +).
Treatment.—Exploratory laparotomy. Intravenous injections of colloidal lead commenced April 15th, 1925. Slight reaction, quick recovery. Total quantity administered 0.75 gram. No scholastic examination missed during treatment.
Subsequent History.—Now alive and well nearly four years later, though some evidence of a small arrested growth to be made out on palpation. At present holding resident hospital appointment.

R. I. 9.—Female, aged 45; unmarried.
Diagnosis.—Sarcoma of third lumbar vertebra, which was destroyed (*x* ray +).
Treatment.—Intravenous injections of colloidal lead commenced July 27th, 1925. Total quantity administered 0.55 gram Pb. Steady improvement. Slight reaction.
Subsequent History.—Now alive and well three and a half years later, except for occasional pain in region of deformity.

352.—Female, aged 66; unmarried.
Diagnosis.—Squamous carcinoma of larynx—left arytenoid (section +).
Treatment.—Intravenous injections of colloidal lead phosphate commenced March 8th, 1928. Total quantity administered approximately 0.5 gram Pb. Slight reaction. Gradual diminution of tumour.
Subsequent History.—Patient is alive and doing well. Last report from laryngologist—Mr. H. V. Forster—(December 10th, 1928): "The left arytenoid from which I removed a piece [previously] . . . is now pale in appearance, and in colour is similar to the right one."

R. I. 39.—Female, aged 37; married; 9-para.
Diagnosis.—Carcinoma of rectum with glands, associated with pregnancy. (No section.)
Treatment.—Exploratory laparotomy and colostomy by Mr. Kennon. Intravenous injections of colloidal lead commenced July 3rd, 1926. Total quantity administered 0.465 gram Pb. Slight reaction. Normal pregnancy and confinement.
Subsequent History.—Premature delivery April, 1928. Patient alive and well two and a half years later. No evidence of disease.

R. I. 102.—Male, aged 60.
Diagnosis.—Squamous carcinoma of floor of mouth (section +). Glands in the neck.
Treatment.—Radium (80 mg.) applied by Mr. Frank Jeans to floor of the mouth for twenty-four hours (August 18th, 1927). Intravenous injections of colloidal lead selenide commenced September 1st, 1927. Total amount administered 0.45 gram Pb. No reaction. Glands in neck gradually disappeared under treatment, and the ulcerated area in floor of mouth healed and thickening disappeared.
Subsequent History.—Patient now alive and well one and a half years later.
Comment.—Improvement and disappearance of primary growth and glands could hardly have been caused by single dose of radium.

N. H. 22.—Male, aged 69.
Diagnosis.—Carcinoma of [illegible] bladder. (No section.)
Treatment.—Exploratory laparotomy by Mr. J. H. Rawlinson. Intravenous injections of colloidal lead commenced August 19th, 1925. Total quantity administered 0.44 gram Pb. Occasional vomiting during treatment.
Subsequent History.—Now alive and well three and a half years later. Some thickening in neighbourhood of scar.

N. H. 53.—Male, aged 59.
Diagnosis.—Carcinoma of splenic flexure of colon. (No section.)
Treatment.—Operation for obstruction by Mr. Oldham, June, 23rd, 1927. Fixed tumour size of orange; numerous glands. Anastomosis. Intravenous injections of colloidal lead commenced August 10th, 1927. Total amount administered 0.55 gram Pb. No reaction noted.
Subsequent History.—Now alive and well one and a half years later. Increased in weight 2 st. No tumour palpable.

N. H. 25.—Male, aged 42.
Diagnosis.—Carcinoma of ampulla of Vater. (No section.)
Treatment.—Gastro-enterostomy by Mr. G. C. Simpson. Intravenous injections of colloidal lead commenced June 8th, 1925. Total quantity administered 0.6 gram Pb. No reaction.
Subsequent History.—Now alive and well three and a half years later. No evidence of disease.

(B) *Treatment of the Primary Growth by Incomplete Operation and the Subsequent Administration of Lead.*

The following cases, in which the growth was primary, are illustrative of partial—that is, *definitely incomplete*—operative procedures, as determined at operation by the recognition of malignant tissue left, or by histological examinations of pieces excised from the edge of the growth removed or from the irremovable part of the growth remaining *in situ*.

192.—Female, aged 60; married; 1-para.
Diagnosis.—Squamous carcinoma of cervix, invasion of parametrium (sections +).
Treatment.—Partial removal by abdominal route on July 18th, 1925. Intravenous injections of colloidal lead commenced August 4th, 1925. Total quantity administered 0.61 gram Pb. Malignant mass left in pelvis observed gradually to disappear. Very slight reaction.
Subsequent History.—Now alive and well three and a half years later.

221.—Female, aged 55; married; 0-para.
Diagnosis.—Carcinoma of body of uterus with three vaginal metastases (sections +).
Treatment.—Hysterectomy by Dr. R. A. Hendry, December 15th, 1924. Intravenous injections of colloidal lead commenced December 31st, 1924. Total quantity administered 0.63 gram Pb. Nodules in vagina observed gradually to disappear. Slight reaction.
Subsequent History.—Patient well for one and a half years, then evidence of regenesis in vagina. Diathermy; mobilization. Patient now well after a further lapse of one and a half years. No evidence of disease.

64.—*Female, aged 47; married; 5-para.*
Diagnosis.—Spheroidal carcinoma of breast, with invasion of muscle and large axillary glands (sections +).
Treatment.—Excision, December 24th, 1922. Intravenous injections of partly colloidal lead iodide commenced January 2nd, 1923. Total quantity administered 0.43 gram Pb. Mobilization. No reaction.
Subsequent History.—Now alive and well six years later.
Comment.—Operation incomplete on examination of specimen (Professor Bloodgood).

N. H. 18.—Female, aged 34; married; 0-para.
Diagnosis.—Columnar carcinoma rectum (section +).
Treatment.—Excision of rectum by Mr. G. C. Simpson, November 17th, 1924. Several adherent glands left on sacrum. Intravenous injections of colloidal lead commenced January 2nd, 1925. Total quantity administered 0.455 gram Pb. No reaction.
Subsequent History.—There has been a recto-vaginal fistula since the operation. Patient now alive and free from disease four years later.

R. I. 4.—Female, aged 52; married; 3-para.
Diagnosis.—Extensive squamous carcinoma cervix (section +).
Treatment.—Vaginal hysterectomy, September 25th, 1924. Disease left in the broad ligaments and to edge of specimen (sections +). Intravenous injections of colloidal lead commenced December 16th, 1924. Total quantity administered approximately 0.5 gram Pb. *No serious reaction.*
Subsequent History.—Now alive and well four years later.

R. I. 70.—Male, aged 51.
[illegible] carcinoma of glands of neck (section +).
[illegible] by Mr. Woolfenden April 27th, 1926, ar[illegible] growth was almost certainly left behind at the second operation. Intravenous injections of colloidal lead selenide commenced February 17th, 1927. Total amount administered 0.465 gram Pb. Slight reaction.
Subsequent History.—Now, nearly two years later, general condition good and there is no evidence of growth.
Comment.—It is hardly possible that the patient was cured by the operations, especially as *the primary growth was never identified*, but was probably in the mouth, which was in an unhealthy condition with papillary stomatitis.

N. H. 27.—Female, aged 37; married; 0-para.
Diagnosis.—Carcinoma of stomach (section +).
Treatment.—Operation by Mr. G. C. Simpson, November 13th, 1925—partial gastrectomy. Glands very much enlarged and hard; not removed. Intravenous injections of colloidal lead commenced December 3rd, 1925. Total quantity administered 0.45 gram Pb. Some reaction.
Subsequent History.—Patient now alive and well and free of symptoms, with gain in weight, 3 years later. No evidence of disease.
Comment.—This case obviously could not have been cured by operation alone as the involved glands were left.

(C) *Cases in which Recurrence occurred after Removal of the Primary Neoplasm, and which were Subsequently Treated with Lead.*

A large proportion of all cases received by us for treatment has included those in which there has been recurrence at some period after operation performed elsewhere. As we have indicated, we prefer to treat the primary growth ourselves in order that treatment may be commenced immediately after operation, rather than to treat patients in whom there is a definite recurrence. In the latter circumstances the patient is usually in poor condition, and the disease is often much more widespread than can

be recognized. These patients are difficult to cure; still we have had a number of apparent successes, a few of which are recorded below. In those cases in which a primary operation performed by others had been followed by recurrence obviously the operation cannot be taken into account as an accessory factor in the ultimate recovery of the patient.

110.—Female, aged 57; married; 5-para.
Diagnosis.—Recurrence after operation for spheroidal carcinoma of right breast (section +).
Treatment.—Excision by Mr. Battle, March, 1922; second operation by Mr. Maynard Smith, May 21st, 1923, for lump above clavicle. Further evidence of recurrence. Intravenous injections of partly colloidal lead iodide and colloidal lead commenced July 27th, 1923. Total quantity administered 0.2065 gram Pb. No reaction.
Subsequent History.—Alive and well five and a half years later.

201.—Female, aged 50; unmarried.
Diagnosis.—Scirrhous carcinoma of left breast with extensive local recurrence on chest wall, glands (section +), and left lung (*x* ray and aspiration).
Treatment.—Intravenous injections of colloidal lead commenced December 16th, 1925. Total quantity administered 0.7 gram Pb. Slight reaction.
Subsequent History.—The extensive disease was considerably reduced, and after two and a half years the general condition of the patient was much improved. Unfortunately she died of acute pneumonia following a chill in August, 1928.

216.—Female, aged 62; unmarried.
Diagnosis.—Recurrent spheroidal carcinoma of left breast involving rib (section +).
Treatment.—Intravenous injections of colloidal lead commenced January 13th, 1926. After 0.3 gram administered, suspension for four months. Scar tissue showed "very atypical regressing almost unrecognizable spheroidal-celled carcinoma." Further injections, making total quantity 0.575 gram Pb. Slight reaction. Later mobilization. Small recurrence removed December 6th, 1928. Radium, followed six days later by an injection, making total quantity 0.6 gram Pb. received.
Subsequent History.—Quite well at the present time.

161.—Female, aged 60; married; 1-para.
Diagnosis.—Scirrhous carcinoma of left breast (section +). Recurrence local and at root left lung (*x* ray, Dr. Finzi).
Treatment.—"Radical" excision by Sir Lenthal Cheatle of left breast, May 12th, 1924. Intravenous injections of colloidal lead commenced August 8th, 1924. Total quantity administered 0.595 gram Pb. Severe delayed reaction after completion—vomiting for fourteen days; then complete recovery.
Subsequent History.—Believed to be now alive and well four and a half years later. Last letter received November, 1926.

169.—Female, aged 47; married; 0-para.
Diagnosis.—Scirrhous carcinoma left breast (section +). Recurrence in supraclavicular and axillary glands, and local.
Treatment.—"Radical" excision by Sir Lenthal Cheatle, January, 1923. *X*-ray applications by the late Dr. A. Reid. Sir Lenthal Cheatle discovered recurrence in August, 1924. Intravenous injections of colloidal lead commenced September 17th, 1924. Some reaction occasionally. Total quantity administered 0.6 gram Pb.
Subsequent History.—Now alive and well four and a half years later.

R. I. 51.—Male, aged 67.
Diagnosis.—Squamous carcinoma of lip (section +) with glands in the neck.
Treatment.—Excision of primary growth by Mr. Woolfenden, May 25th, 1926, and excision of glands by Mr. Nuttall, July 9th, 1926. Definite recurrence two months later: a large hard fixed mass in neck. Intravenous injections of colloidal lead commenced September 11th, 1926. Total amount administered 0.4 gram Pb. No reaction.
Subsequent History.—Now alive and well, no evidence of disease nearly two and a half years later.

(D) *Treatment of the Primary Growth by Operation and the Subsequent Administration of Lead.*

The next group we shall consider is that in which operation for the primary growth was performed in Liverpool, with three exceptions, and the patients treated immediately. This method has, of course, been largely employed, and the successful results are many; consequently we naturally prefer to treat cases of malignant disease ourselves from the time the diagnosis is first made. It must, of course, be admitted that in some of the patients the disease may have been entirely removed at operation. An attempt will be made to indicate the chances of this occurrence in regard to the cases described; in many it will be obvious that the prognosis subsequently to operation alone would have been very bad. Moreover, the character of the operation must be taken into account—for example, vaginal hysterectomy for cancer of the cervix, of which the first four are examples.

30.—Female, aged 31; widow; 3-para.
Diagnosis.—Squamous carcinoma of cervix (section +).
Treatment.—Amputation of cervix, October 9th, 1921. Intravenous injections of partly colloidal lead iodide commenced November 1st, 1921. Total quantity administered 0.768 gram Pb. No reaction. Subsequently vaginal hysterectomy—safety measure—December 4th, 1922; no evidence of cancer found (sections −).
Subsequent History.—Now alive and well more than seven years later.
Comment.—Operation alone might have cured this patient, but her youth made prognosis unfavourable.

139.—Female, aged 49; widow; 1-para.
Diagnosis.—Squamous carcinoma of cervix (section +).
Treatment.—Vaginal hysterectomy, February 24th, 1924. Intravenous injections of colloidal lead and partly colloidal lead iodide commenced March 7th, 1924. Total quantity administered approximately 0.3 gram Pb. No reaction.
Subsequent History.—Now alive and well nearly five years later.
Comment.—Prognosis after operation alone was unfavourable owing to the advanced stage of the disease.

155.—Female, aged 42; married; 6-para.
Diagnosis.—Squamous carcinoma of cervix (section +).
Treatment.—Vaginal hysterectomy, June 17th, 1924. Involvement of the parametrium probable. Intravenous injections of colloidal lead commenced July 9th, 1924. Total quantity administered 0.21 gram Pb. No reaction.
Subsequent History.—Now alive and well four and a half years later.
Comment.—Prognosis after operation alone would have been unfavourable. The small quantity of lead administered was due to the fact that the patient suffered with old renal damage before treatment commenced.

R. I. 82.—Female, aged 58; married; 6-para.
Diagnosis.—Extensive squamous carcinoma of cervix (section +). Mitral stenosis; hyperpiesis. Wassermann reaction ++.
Treatment.—Vaginal hysterectomy, May 16th, 1927. Intravenous injections of colloidal lead selenide commenced May 26th, 1927. Total quantity administered 0.37 gram Pb. Slight reaction. Blood pressure raised.
Subsequent History.—Alive; no evidence of pelvic disease more than one and a half years later.

In view of the great malignancy of sarcoma uteri, apart from the spindle-celled variety arising in fibromyoma, the following cases are of interest.

88.—Female, aged 61; unmarried; nursing sister.
Diagnosis.—Mixed-cell sarcoma of uterus (section +) and carcinoma of right ovary (section +).
Treatment.—Abdominal panhysterectomy with removal of appendages, April 28th, 1923. Intravenous injections of partly colloidal lead iodide commenced May 8th, 1923. Total quantity administered 0.2 gram Pb. No reaction.
Subsequent History.—Now alive and well over five and a half years later.
Comment.—The small quantity of lead administered was due to the diminutive size of the patient and her frailty.

C. I. 1.—Female, aged 59; unmarried.
Diagnosis.—Large round and multinucleated celled sarcoma of the uterus (section +).
Treatment.—Panhysterectomy with right salpingo-oöphorectomy, January 22nd, 1927. Intravenous injections of colloidal lead commenced February 12th, 1927. Total quantity administered 0.4 gram Pb. No reaction.
Subsequent History.—Now alive and well two years later, a period of time sufficient to state that the patient is "clinically cured" of this form of malignant disease.

The following cases of advanced carcinoma mammae with involvement of the axillary glands, in which the prognosis after operation alone would have been extremely grave, seem to be worth placing on record.

57.—Female, aged 38; married, 4-para.
Diagnosis.—Spheroidal-celled carcinoma of left breast and axillary glands (sections +).
Treatment.—"Radical" operation, November 13th, 1922. Intravenous injections of colloidal lead commenced November 21st, 1922. Total amount administered 0.578 gram Pb. No reaction. Mobilization.
Subsequent History.—Right breast excised October 27th, 1924; "chronic mastitis" (section −). Patient now alive and well six years later.
Comment.—Prognosis after operation alone very grave.

221.—Female, aged 59; widow; 0-para.
Diagnosis.—Spheroidal-celled carcinoma of left breast and axillary glands (sections +).
Treatment.—"Radical" operation, December 29th, 1925. Intravenous injections of colloidal lead commenced January 5th, 1926. Total quantity administered 0.6 gram Pb. No reaction.
Subsequent History.—Now alive and well three years later.
Comment.—Prognosis after operation alone most unfavourable.

240.—Female, aged 52; married; 2-para.
Diagnosis.—Spheroidal-celled carcinoma of right breast and axillary glands (sections +).
Treatment.—"Radical" operation, February 26th, 1926. Intravenous injections of colloidal lead commenced March 2nd, 1926.

Total quantity administered 0.685 gram Pb. Rather severe vomiting in earlier part of treatment.
Subsequent History.—Now alive and well nearly three years later.
Comment.—Prognosis after operation alone bad.

244.—Female, aged 72; unmarried.
Diagnosis.—Spheroidal-celled carcinoma of right breast and axillary glands (sections +).
Treatment.—"Radical" operation, March 15th, 1926. Intravenous injections of colloidal lead commenced March 26th, 1926. Total quantity administered 0.575 gram Pb. Some gastro-intestinal disturbance after the earlier injections, from which patient quickly recovered.
Subsequent History.—Now alive and well nearly three years later.
Comment.—Prognosis after operation alone grave.

237.—Female, aged 54; widow; 6-para.
Diagnosis.—Spheroidal-celled carcinoma of breast and axillary glands (sections +).
Treatment.—"Radical" operation, November 25th, 1926. Intravenous injections of colloidal lead and lead selenide commenced December 1st, 1926. Last dose of colloidal lead phosphate. Total quantity administered 0.555 gram Pb. No reaction.
Subsequent History.—Now alive and well over two years later.
Comment.—A very bad case. Prognosis after operation alone very bad.

The following cases, which may also be briefly recorded, are of some interest. In most the wide extent of the growth is well shown in photographs taken before treatment. They are all alive and well at the present time.

82.—Male, aged 51.
Diagnosis.—Squamous carcinoma of tongue, fauces, soft palate, glands of neck (sections +).
Treatment.—"Radical" operation, March 14th, 1923. Intravenous injections of partly colloidal lead iodide commenced March 22nd, 1923. Total quantity administered 0.56 gram Pb. No reaction. Mobilization later.
Subsequent History.—Now alive and well six years later.
Comment.—Extent, nature, and situation of disease made prognosis after operation alone extremely grave.

333.—Male, aged 68.
Diagnosis.—Squamous carcinoma of face (section +).
Treatment.—Excision with diathermy, June 26th, 1927. Intravenous injections of colloidal lead, lead selenide, and lead phosphate commenced July 3rd, 1927. Total quantity administered 0.55 gram Pb. No reaction.
Subsequent History.—Now alive and well more than one and a half years later. All spots are fast disappearing.
Comment.—Might have been cured by operation so far as the growth was concerned.

327.—Male, aged 64.
Diagnosis.—Basal-celled carcinoma of face (section +).
Treatment.—Diathermy excision May 18th, 1927. Intravenous injections of colloidal lead and lead phosphate commenced May 28th, 1927. Total quantity administered 0.33 gram Pb. No reaction.
Subsequent History.—The diathermy cautery was used on several subsequent occasions. Now alive and well, with much contracture of face, nearly two years later.
Comment.—Unlikely that operation alone would have proved successful.

R. I. 32.—Male, aged 62; medical practitioner.
Diagnosis.—Carcinoma of sigmoid (section +) with involvement of glands.
Treatment.—Excision of sigmoid and portion of adherent small bowel with some glands by Mr. Woolfenden, January 22nd, 1926. Temporary colostomy. Intravenous injections of colloidal lead commenced February 3rd, 1926. Total quantity administered 0.35 gram Pb. Never any serious reaction.
Subsequent History.—Now alive and well three years later; has gained weight; no evidence of disease.
Comment.—At the operation it was considered extremely unlikely that all the numerous glands were removed.

R. I. 17.—Female, aged 23; unmarried.
Diagnosis.—Carcinoma of vulva (section +).
Treatment.—"Radical" operation, January 21st, 1926. Intravenous injections of colloidal lead commenced February 3rd, 1926. Total quantity administered 0.525 gram Pb. Never any serious reaction.
Subsequent History.—Now alive and well three years later.
Comment.—The extreme youth of the patient in connexion with cancer of the vulva must be almost unique. Prognosis would, therefore, seem to have been bad subsequent to operation only.

R. I. 21.—Female, aged 64; married; 5-para.
Diagnosis.—Epithelioma of the thigh (section +).
Treatment.—Ulcerated growth excised by Mr. Jeans, February 12th, 1926; muscle involved. Intravenous injections of colloidal lead commenced March 16th, 1926. Total amount administered 0.3 gram Pb. No reaction.
Subsequent History.—Now alive and well three years later.
Comment.—This patient may have been cured by operation alone.

R. I. 29.—Female; aged 70; unmarried.
Diagnosis.—Carcinoma of body of uterus with fibromyomata (section +).
Treatment.—Operation April 22nd, 1926; panhysterectomy with removal of appendages. Intravenous injections of colloidal lead commenced May 25th, 1926. Total quantity administered 0.425 gram Pb. Very slight reaction.
Subsequent History. Now alive and well nearly three years later.
Comment.—This patient would in all probability have been cured by operation alone.

R. I. 100.—Male, aged 72.
Diagnosis.—Epithelioma of soft palate (section +).
Treatment.—Ulcer excised by Mr. Frank Jeans with diathermy August 19th, 1927. Intravenous injections of colloidal lead selenide commenced August 27th, 1927. Total amount administered 0.3 gram Pb. Some reaction after some injections, with oedema of ankles and cramps in legs.
Subsequent History.—Patient now alive and well one and a half years later.
Comment.—It is possible that this case was cured by operation, but the situation of the growth makes it unlikely that he was cured by such simple procedure.

R. I. 54.—Female, aged 59; married; 1-para.
Diagnosis.—Epithelioma of vulva (section +).
Treatment.—"Radical" excision of the whole of vulva including orifice of urethra, September 16th, 1926. Intravenous injections of colloidal lead commenced October 2nd, 1926. Total amount administered 0.45 gram Pb. Very slight reaction.
Subsequent History.—Now alive and well, no recurrence, nearly two and a half years later.
Comment.—The disease was so extensive that cure by operation was extremely unlikely.

N. H. 11.—Female, aged 39; married; 1-para.
Diagnosis.—Carcinoma of stomach (section +).
Treatment.—Operation by Mr. G. C. Simpson, September 26th, 1924. Growth hard, adherent to pancreas. Partial gastrectomy; gastro-enterostomy. Intravenous injections of colloidal lead commenced October 17th, 1924. Total quantity administered 0.46 gram Pb. No reaction.
Subsequent History.—Now alive and well nearly four and a half years later.
Comment.—This patient was not regarded as being curable or cured by operation alone.

N. H. 44.—Male, aged 50.
Diagnosis.—Sarcoma of cheek (section +).
Treatment.—Operation by Mr. Oldham, August 2nd, 1926 (*see Lancet*, 1928, i, 28). Intravenous injections of colloidal lead commenced October 25th, 1926. Total amount administered 0.55 gram Pb. Slight reaction.
Subsequent History.—Patient now alive and well over two years later.

N. H. 38.—Male, aged 40.
Diagnosis.—Carcinoma of colon (section +).
Treatment.—Operation by Mr. Rawlinson, May 29th, 1926. Large growth in the descending colon with abscess formation. Excision. Temporary colostomy. Later anastomosis. Intravenous injections of colloidal lead commenced June 8th, 1926. Total amount administered 0.225 gram Pb. No reaction.
Subsequent History.—Patient now alive and well two and a half years later. No sign of disease.
Comment.—It is unlikely that such an advanced case of cancer of the bowel would have been cured by operation alone.

N. H. 40.—Male, aged 61.
Diagnosis.—Carcinoma of colon (section +).
Treatment.—Operation by Mr. Monsarrat, August 3rd, 1926. Large growth in pelvic colon. No enlarged glands. Resection. Intravenous injections of colloidal lead commenced August 20th, 1926. Total amount administered 0.575 gram Pb. No reaction.
Subsequent History.—Now alive and well two and a half years later. No evidence of recurrence.

The next three cases, which are very briefly recorded, were all subjected to operation elsewhere, and were referred to us subsequently for treatment, in view of the fact that they were cases in which recurrence was expected owing to the extreme malignancy of neoplasms of these types. Histological examination was made in each case.

219.—Male, aged 47.
Diagnosis.—Melanoma of left eye (section +).
Treatment.—Operation, December 11th, 1925. Removal of eye by Sir William Lister. Intravenous injections of colloidal lead commenced January 18th, 1926. Total quantity administered 0.5 gram Pb. Slight reaction.
Subsequent History.—Patient is alive and well more than three years later.

223.—Male, aged 36.
Diagnosis.—Carcinoma of right testicle (section +).
Treatment.—Operation by Dr. Roughton, January 4th, 1926. Excision of testicle. Intravenous injections of colloidal lead commenced January 26th, 1926. Total quantity administered 0.625 gram Pb. Mobilization a year later. Slight reaction; nausea.
Subsequent History.—Now alive and well three years later.

337.—Male, aged 26.
Diagnosis.—Periosteal sarcoma of right tibia (section +).
Treatment.—Operation by Mr. Page, London, June 20th, 1927. Amputation through middle of thigh. Intravenous injections of

colloidal lead, colloidal lead selenide, and colloidal lead phosphate commenced September 2nd, 1927. Total quantity administered 0.543 gram Pb. Very slight reaction.

Subsequent History.—Now alive and well nearly one and a half years later.

(E) *Treatment of Primary Neoplasm with Lead and X Rays.*

Of the cases treated in this way the first two are of special interest in that regenesis of the growth occurred whenever treatment with lead was suspended, and in these circumstances the *x* rays appeared to be ineffective until further administration of lead was practised. This is not shown in the abbreviated notes below.

133.—Male, aged 8.

Diagnosis.—Sarcoma of the scapula (section +). Involvement of axillary glands.

Treatment.—Intravenous injections of colloidal lead commenced January 29th, 1924. *X*-ray treatment commenced April 29th, 1924. In July an *x*-ray picture showed considerable improvement in the scapula. Reossification. Improvement maintained in report dated January 23rd, 1925. Treatment suspended. April 27th, 1925, regenesis of tumour. Further treatment. Total quantity administered 0.2475 gram Pb. Slight reaction.

Subsequent History.—Death of patient reported June 26th, 1925.

Comment.—It now appears that the treatment of lead should not have been suspended when so small a quantity as 0.1725 gram had been administered. The age of the patient, and the size of the child, made it difficult to decide, in view of improvement.

114.—Male, aged 18.

Diagnosis.—Round-celled sarcoma of the scapula (section +).

Treatment.—Intravenous injections of colloidal lead commenced August 10th, 1923. Rapid increase in size of tumour in next three weeks. X-ray treatment commenced. On November 16th, 1923, marked clinical improvement; maintained till end of year. Treatment suspended. March 28th, 1924, recurrence below glenoid noted. Further treatment with lead and *x* rays. July 3rd, 1924, improvement with reossification. Treatment again suspended. August 5th, 1924, destructive bone changes again taking place. Further treatment till December 2nd, 1924. Total quantity of lead administered 0.415 gram. Slight reaction. November 20th, 1924, report: "This patient now undoubtedly doing well. Supraclavicular and axillary swellings disappeared; the size of the scapula is almost normal."

Subsequent History.—Patient disappeared. Was reported dead, of recurrence in the spine, September 18th, 1925.

R. I. 121.—Male, aged 14.

Diagnosis.—Periosteal sarcoma of femur (no section; *x*-ray and clinical evidence).

Treatment.—Intravenous and intra-arterial injections of colloidal lead phosphate commenced June 11th, 1928. Total amount administered up to last injection, October 25th, 1928, 0.412 gram Pb. No reaction. Three injections (0.16 gram Pb) were given directly into femoral artery. X-ray application four days after the last three injections.

Subsequent History.—The condition of the patient is good. The tumour has decreased in size, but it is too early to state ultimate fate. So long ago as June, 1928, Professor Kelly considered the case quite hopeless, and that the duration of life could not be many weeks.

R. I. 125.—Male, aged 33.

Diagnosis.—Fixed mass carcinoma of femoral glands (section +), secondary to carcinoma of foot.

Treatment.—Intravenous and intra-arterial (femoral) injections of colloidal lead and lead aspartate commenced August 29th, 1928. Total quantity at present administered 0.46 gram Pb. Slight reaction. *X* rays applied four days after each of the injections of lead.

Subsequent History. Too soon for prognosis. Tumour in groin smaller, soft, and movable.

Comment.—Of interest because of arterial route employed.

N. H. 2.—Male, aged 28.

Diagnosis.—Recurrence of carcinoma of testicle (section +). Mass in groin.

Treatment.—Excision of left testicle by Mr. G. C. Simpson two years previously, followed by *x*-ray applications. Recurrence. Intravenous injections of colloidal lead commenced August 12th, 1924. Total quantity administered 0.265 gram Pb. No reaction.

Subsequent History.—Now alive and well four and a half years later. No evidence of disease.

140.—Male, aged 34.

Diagnosis.—Mixed-cell sarcoma of the scapula and axillary glands (section +).

Treatment.—Intravenous injections of colloidal lead commenced March 7th, 1924. After seven doses *x*-ray treatment begun. Eighteen *x*-ray applications in all in conjunction with further intravenous injections of lead. Total quantity administered 0.2 gram Pb. No reaction.

Subsequent History.—Patient is alive and well five years later.

331.—Female, aged 72; unmarried.

Diagnosis.—Lymphosarcoma of left groin.

Treatment.—Tumour excised June 24th, 1927. Intravenous injections of colloidal lead selenide and colloidal lead commenced June 28th, 1927. Recurrence noted January, 1928. Patient not seen for four months. June 12th, 1928, recurrence adherent to the femoral artery and vein; removed with difficulty. Further course of lead phosphate injections administered together with *x*-ray therapy. Total quantity of lead administered approximately 0.6 gram, and five *x*-ray applications. No reaction to injections.

Subsequent History.—Patient has put on weight, and at the present time there is no evidence of recurrence.

R. I. 75.—Male, aged 52.

Diagnosis.—Lymphosarcoma of pharynx, roof of mouth, and cheek (section +).

Treatment.—Intravenous injections of colloidal lead commenced March 18th, 1927. Total amount administered approximately 0.6 gram Pb. No reaction. Last injection February 15th, 1928. Eight doses of *x* rays applied to right side of the face, and three doses applied to neck on the right side.

Subsequent History.—Now alive and well nearly two years later.

STATISTICS AND RESULTS.

In any assessment of the results of the treatment of human disease, and especially of malignant disease, we are confronted with so many variable factors—site of neoplasm, type of growth, stage of the disease, whether it be primary or secondary, the constitutional condition of the patient, the psychology and experience of the medical attendant, and the rest—that no statistical survey of grouped or general results which takes into consideration a less number than several millions of cases can be more than suggestive. So it is clear that when a practitioner, inexperienced in the method employed, fails in 25 or 50, or even 100 cases, to secure a single completely satisfactory result, as very easily may happen with a new method of treatment, it must be remembered that negative evidence of that sort can never be weighed in the balance against that which is positive.

It has seemed to us, then, that at the present time the clear enunciation of many positives in a variety of circumstances may set in motion philosophical reflection in minds trained to apprehend.

In the following table details of general interest are presented in a simple manner in order that no confusion may be created as to the results recorded, or objections raised on the score of incompleteness of information, as has happened without justification in the past,[8] in spite of the fact that we have on several occasions[1 2 3 4] published full statements of our methods and results, with illustrative cases.

Table of Results.

November 9th, 1920–November 9th, 1928.

1. Total number of cases treated		566*
2. Died of the disease before treatment could be completed		359
(*a*) Received less than 0.25 gram Pb ...	198	
(*b*) Received more than 0.25 gram Pb, but less than 0.5 gram	161	
3. Died of the disease after treatment concluded ...		77
4. Died of intercurrent affections, while under treatment		7
5. Died as result of extensive destruction of disease...		5
6. Complete treatment refused		22
7. Too recent for results to be estimated		31
8. Believed cured, but died of other affections (1 from apoplexy, 4½ years' interval; 1 from toxæmia of pregnancy, nearly 5½ years' interval)		2+
9. Disease completely arrested		12+
10. Believed cured and treatment stopped		51+

* At the conference in London in July, 1928, speaking from memory, I stated that about 1,000 patients had come under our care in Liverpool. This number is a little in excess of the exact figure. Many cases additional to those given above, however, and recorded in previous tables as "died before treatment could be commenced," and a further number rejected after consultation and examination, help to bring the total of cases seen nearer to the number stated.

In any estimate of results the serious type of case for the most part treated must be clearly remembered; it may be described as consisting largely of that in which the condition was considered hopeless. Ignoring, however, any consideration of temporary benefit—amelioration of symptoms and prolongation of life, or fatal destruction of the neoplasm—it appears that we have 303 cases to consider (items 2 (*b*), 3, 8, 9, and 10), cases which received more than one-half of the minimum treatment advised. Seventy-seven (77) died after full treatment; consequently it might be argued that there were 65 successes as opposed to 77 failures. Moreover, we have reason to believe that at least 40 per cent. of the "*too-recent*" cases will terminate favourably. Nevertheless, to put our statistics in the worst possible light, we can state that there were 65 successes out of 303 cases treated—that is, 21.5 per cent. of successful results.

CONCLUSION.

In conclusion we may urge two points, the recognition of which seems to us to be of paramount importance in the consideration of the treatment of malignant disease with lead at the present time.

First, no one in his senses would care to suggest that the possession of a knife and a few instruments is all that is required for the surgical cure of cancer of the stomach. Yet some seem to think that for lead therapy in this disease all that is required is that lead shall be pumped into the veins of the sufferer. We now realize that it was not the fault of radium that it was of so little clinical use twenty years ago.

Second, the scientifically minded inquirer will not demand that a new method of treatment for cancer operating on the worst and most advanced types of cases shall give far *better initial statistical results* than those obtainable with other long-established and standardized forms of treatment acting on early and selected cases; but, if it should do so, those capable of appraising evidential values will appreciate the vast possibilities that await full and proper development of the method tested.

I have to thank my colleagues Dr. Leslie Cunningham, Mr. J. B. Oldham, Dr. S. B. Herd, and Dr. M. Datnow, not only for the careful way in which they have conducted the laborious task of analysing the case records and tracing the fate of the patients, but also for co-operation in the clinical work, much of which has been conducted *entirely on their own initiative and responsibility.*

CHOLECYSTOGRAPHY.

AN ANALYSIS OF 137 CASES SHOWING THE RELIABILITY OF THE ORAL METHOD.

BY

T. GARRATT HARDMAN, M.D. DUB. UNIV.,

RADIOLOGIST TO THE MERCER'S, THE RICHMOND, AND THE ROYAL CITY OF DUBLIN HOSPITALS.

(With Special Plate.)

I HAVE been stimulated to write this paper by the repeated inquiries of my colleagues and other members of the profession as to how much one may expect from the *x*-ray examination of the gall-bladder, and with special reference to what is termed the "Graham-Cole test." Up to a few years ago the radiographic examination of the gall-bladder had been most unsatisfactory, and results were so uncertain that little reliance could be placed upon them. No routine examination of the gall-bladder was carried out in hospitals, and one was rarely asked to attempt such an investigation in private practice. To the late Drs. Carman of Rochester and Robert Knox of London, Case, George, and others in America and on the Continent, is due the credit for valuable pioneer work done in connexion with the radiography of the gall-bladder by direct methods. The detection of gall-stones could be made with more certainty in those large hospitals or clinics which were heavily endowed with funds than in the smaller and less favoured institutions. Where it was possible to take a large number of films under varying conditions of tube penetration, exposure, etc., the chances of obtaining positive evidence of pathological conditions involving the gall-bladder were proportionately greater. But even in the most favourable circumstances the direct method of examination yielded only 37 per cent. of correct diagnoses. The normal gall-bladder casts no shadow in even the most technically perfect films. It was maintained, therefore, that if a shadow of the gall-bladder was shown upon a film it was an indication of pathology; that the walls were abnormally thickened, the contents of unusual density, or that multiple calculi were present. This was probably true, and when positive shadows were obtained they were of definite diagnostic value. It was exceptional, however, to see such shadows in even the best films, and the absence of a shadow did not exclude disease, hence such a finding was of little value. The detection of gall-stones before the days of cholecystography depended upon the composition of the stones. If they contained sufficient calcium they produced well-defined shadows. Some were annular in form, depending upon the denser periphery of the stone, others cast a laminated shadow or concentric rings of dense and less dense material. Others, again, were more homogeneous and faceted. If the gall-bladder was filled with stones even of low density a faint, mottled shadow was sometimes shown. From time to time such radiographs were obtained, but were of rather rare occurrence, and were therefore looked upon more or less as curiosities.

In 1914 Cole called attention to the secondary manifestations of cholecystitis as revealed by the opaque meal, and these findings were further elaborated by George and others. Information so obtained, together with the direct visualization of stones, as already described, formed the basis for *x*-ray diagnosis of gall-bladder disease up to the year 1924. In February, 1924, Graham, Cole, and Copher of St. Louis announced the success of their work in demonstrating the gall-bladder radiographically after the intravenous injection of tetrabromphenolphthalein. In a further communication[2] in 1925 these authors discuss the theory and application of this new method of examination:

"This procedure is based upon the theory that if any substance containing a metal or atoms of bromine, or iodine, can be introduced into the gall-bladder in sufficient concentration, then this organ would be made opaque to *x* rays. The substance must be one which can be given either by the alimentary canal or by injection. It would have to be a substance which would be excreted by the liver and carried to the gall-bladder in the bile. Moreover, the ability of the gall-bladder to concentrate its contained bile would indicate that a sufficient time must elapse before a shadow of maximal density would occur. Reasoning *from these premisses, the conclusion would have to be* drawn that the shadows of sharpest contrast would be obtained in normal individuals. Similarly also no shadow would be expected to appear if the liver were unable to excrete the substance in sufficient amount, if the cystic duct were occluded or if the function of the gall-bladder were sufficiently impaired to prevent the concentration of the material."

Such is the theory of cholecystography as briefly outlined by Graham, Cole, and Copher. As the object of this paper is to demonstrate by practical statistics the reliability of cholecystography by the oral method in particular I do not wish to lengthen my communication unduly by recounting in detail the history of its development or the chemistry of the drugs used. No paper on this subject would, however, be complete without describing the Graham-Cole technique as first practised. In January, 1925, Graham used the tetraiodo-phenolphthalein sodium salt, and claimed superiority for this over the bromine salt in that it cast a denser shadow, a smaller dose was sufficient, and the toxicity was lessened in virtue of the reduced dose.

Technique of Intravenous Method.—In 30 c.cm. of freshly distilled water 3.5 *grams of the salt are dissolved.* The solution after filtration is sterilized in a boiling water bath for 15 minutes. It is given intravenously in two doses, half an hour apart, in the morning before breakfast, between 7.30 and 9 o'clock. Care should be taken not to allow extravasation outside the vein, as sloughing of tissue may occur. Certain orders are given to the patient and are essential:

1. Breakfast and lunch should be omitted.
2. Protein should be omitted from the evening meal.
3. Water is allowed *ad libitum*.
4. Stomach contents should be made alkaline by frequent doses of sodium bicarbonate.

The rationale of the latter procedure is explained in an article by Cole, who found experimentally on dogs that the flow of bile into the intestines through relaxation of the sphincter of Oddi is prevented by keeping the contents of the stomach alkaline. This probably tends to promote the concentration of bile in the gall-bladder. Films are taken at four, eight, twenty-four, and thirty-two hours after injection. A normal gall-bladder will begin to cast a shadow in four hours. This will be faint, but should reveal the

contour of the normally shaped organ. From sixteen to twenty-four hours the shadow becomes denser but the gall-bladder smaller in size. From that time onwards the shadow diminishes in density until the forty-eighth hour, when no dye should remain.

Interpretation.—If no shadow is obtained any of the following conditions may be present.

1. Serious disturbance of hepatic function resulting in insufficient secretion of the dye to cast a definite shadow. The gall-bladder may not be appreciably altered.
2. Obstructed ducts: (*a*) hepatic, (*b*) cystic, (*c*) common. In the case of the last the absence of shadow is said to be due to excessive diffusion of the dye in a large accumulation of bile.
3. A failure to concentrate bile as a result of inflammatory obliteration of the lymphatic vessels in the walls of the gall-bladder.
4. Multiple stones. If the gall-bladder is filled with stones the amount of dye which enters it may be insufficient to cast a shadow.

If the shadow is faint at the period when it should show a maximal density, or if the shadow is late in appearing, or persists for an abnormally long time, cholecystitis is said to be the cause. In my opinion, however, based upon my own experience, any of the conditions which have already been enumerated may be present, and I do not think it is possible to make a differential diagnosis. Stones which cannot be detected by ordinary radiography owing to their low density and extreme translucency may be by this method clearly demonstrated. I do not say that all can be visualized, but a proportion of them can be shown which would otherwise be missed.

The detection of stones depends upon: (1) their density in relation to the dye-stained bile; (2) the number of stones in the gall-bladder; (3) the situation of the stones—that is, whether in ducts or gall-bladder. If the stones are of very low density, and are not tightly packed, they will appear as discrete clear areas in the dye-filled gall-bladder. If in great numbers and the bladder is completely filled the entry of the dye will be prevented and no shadow will be seen. Stones showing as clear areas in the dye-filled gall-bladder are spoken of as "negative" shadows. If the stones possess calcium in their composition they may appear as discrete opacities in the gall-bladder, and are referred to as "positive" shadows. A proportion of stones will cast definite "ring" shadows with clear centres. If a stone is impacted in the cystic duct it may be visualized by the deposition of dye-stained bile upon it, while the absence of any gall-bladder shadow indicates the obstruction caused by the stone. Stones in hepatic and common ducts may be revealed in a similar way.

It is conceivable that a proportion of stones may be of such a density that they occupy an intermediate position between the extremely translucent and the moderately opaque. Such stones may be present in a dye-filled gall-bladder without casting either negative or positive shadows, and these will therefore be missed by any method of examination. It is probable that they are not of frequent occurrence, but they are bound to cause disappointment in some cases, even when the most careful technique has been observed.

The interpretation of cholecystographic findings just given is equally applicable to the intravenous and oral methods of examination. Using the intravenous method, Graham, Cole, and Copher, in a series of 80 patients upon whom operations had been performed, found the *x*-ray diagnosis to be correct in 96.25 per cent. of the cases. Although the results were so good, there were certain objections to this particular method. In some patients toxic reactions occurred, varying from nausea or slight dizziness to a condition of temporary collapse with a rapid fall in blood pressure. By using the tetraiodo-phenolphthalein instead of the bromine salt these unpleasant reactions have been almost eliminated. Nevertheless, the possibility of such reactions and the fact that the intravenous method required a certain amount of surgical skill, as well as the usual aseptic precautions, to some extent acted as a deterrent to the general use of cholecystography. In collaboration with my colleagues in Mercer's and Richmond Hospitals a small number of cases were examined by the intravenous method during the year 1925, but the results were not very satisfactory, and were not proved to be reliable by operation. I do not wish, however, on this account to condemn the method. First attempts are usually unsuccessful, and I have no doubt that our failures were due to faulty technique or defective drugs. In January, 1925, Whitaker and Milliken of Boston described their results in the oral administration of tetraiodo-phenolphthalein. This was followed from time to time by communications from other workers in America and elsewhere, testifying to the good results obtained by this method, and to-day it has become a routine procedure, and I think I am correct in saying that in this country, at all events, it has replaced the intravenous method.

It was some time before a satisfactory and stable drug could be produced. It acted as a severe gastric irritant, and for this reason it was necessary to enclose the drug in a pill, or capsule, which would pass through the stomach without dissolving. Chemists had many difficulties to overcome, but it is not my purpose to refer to them in this paper. Suffice it to say that many firms are now making keratin-coated capsules which are giving very satisfactory results. Each capsule contains 5 grains of the iodine salt, and the total quantity given varies from 35 to 50 grains, according to body weight. Even this method is not entirely free from unpleasant reactions, but at the worst these only take the form of nausea, with occasional vomiting and diarrhoea, and usually pass off in the course of a few hours. If this difficulty has not already been solved, I believe it will very soon be overcome by using a suspension of the tetraiodo-phenolphthalein in a finely divided condition, as described by Levyn and Aaron.[4] Upon the addition of fruit juice a freshly precipitated acid is formed which is easily converted into a soluble salt by the alkaline duodenal contents. It is claimed that this method causes none of the unpleasant reactions associated with the taking of capsules.

The precise technique adopted varies with different workers, but I have found the procedure recommended by Stewart and Ryan[3] to be very successful, and all my cases since January, 1926, have been examined according to this method.

Oral Technique.

An aperient should be given twenty-four hours before the ingestion of the capsules. On the morning following, a preliminary examination of the gall-bladder should be made. (This part of the Stewart technique I have usually omitted in order to save time, but when possible it is the ideal to be followed.) The usual lunch is allowed. At 6.30 p.m. the following meal is advised: thick soup, creamed chicken, bread-and-butter, and a glass of milk. The abundance of fat in this food will partially or completely empty the gall-bladder in from one to two hours. It is then in [illegible] for the opaque bile. At 9.15 p.m. half a [illegible] bicarbonate in half a glass of water is given. Commencing at 9.30 p.m., two kerasol capsules are given with half a glass of water every fifteen minutes until the complete number has been taken. The patients are instructed not to bite the capsules, but to swallow them whole. Two or three glasses of water may be taken gradually after the ingestion of the capsules. No aperient is allowed until the examination is completed, and no food is allowed until after the second radiographic examination has been made. The patients come for examination at 9.30 the following morning, and again at 1.30 or 2 p.m. Ordinary food is then allowed, and, if desired, another film may be taken an hour later. This I generally omit. A final observation is made at 9.30 the following morning—that is, thirty-six hours after ingestion of the capsules. Radiographs are taken with the patient lying prone on the Potter-Bucky diaphragm, and exposures should be short enough to allow the patient to hold the breath with ease. This is very essential, as the slightest respiratory movement may be sufficient to prevent the proper visualization of the gall-bladder, and if stones are present there will be little chance of demonstrating them. In normal cases the shadow should appear at the twelfth hour, should be smaller and slightly denser at the sixteenth hour, and should be gone in thirty-six hours, or only very faintly seen. The success of the method depends upon the most careful attention to details. For this reason I have printed instructions which are kept by the ward sisters in my hospitals. In my private practice, whenever possible, I like to interview the patient personally the day before examination, so that I can elicit the co-operation and explain the instructions. The points to stress are, "no food and no aperient until permission is given." Failure to observe these instructions has in several cases produced a "no shadow" result, which could not therefore be accepted as reliable, and necessitated a complete repetition of

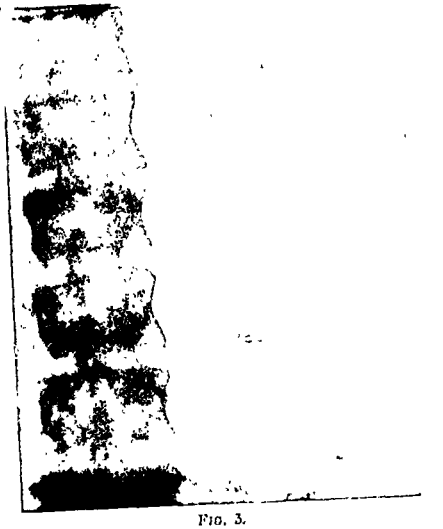

FIG. 3.

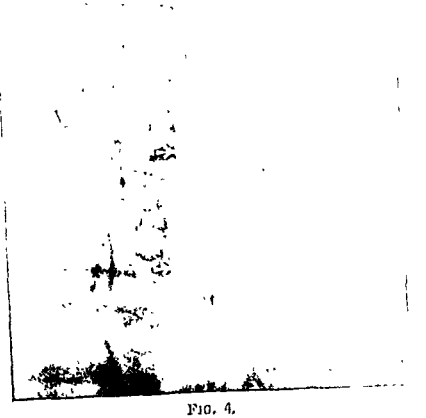

FIG. 4.

DESCRIPTION OF FIGURES.

FIG. 1.—Showing the outline of the normal gall-bladder, filled with the dye, at the lateral margin of the psoas muscle, beneath the shadow of the twelfth rib.

FIG. 2.—Shadow of dye-filled gall-bladder mottled by clear areas, signifying the outlines of stones in the opaque bile.

FIG. 3.—No dye has reached the gall-bladder; the outline of a stone can be clearly *seen* below the shadow of the transverse process of the third lumbar vertebra; this stone was in the common *duct*. A shadow is also to be seen above the upper border of the twelfth rib; it was cast by a stone recovered from the hepatic duct.

FIG. 4.—Multiple stones in the gall-bladder.

FIG. 5.—Same case as Fig. 4. Serial radiograms show a filling defect in the duodenal bulb, caused by pressure of the dye-filled gall-bladder, whose shadow is seen in the left upper angle of each film.

G. P. CROWDEN AND H. A. HARRIS: EFFECT OF OBSTRUCTED RESPIRATION ON HEART AND LUNGS.

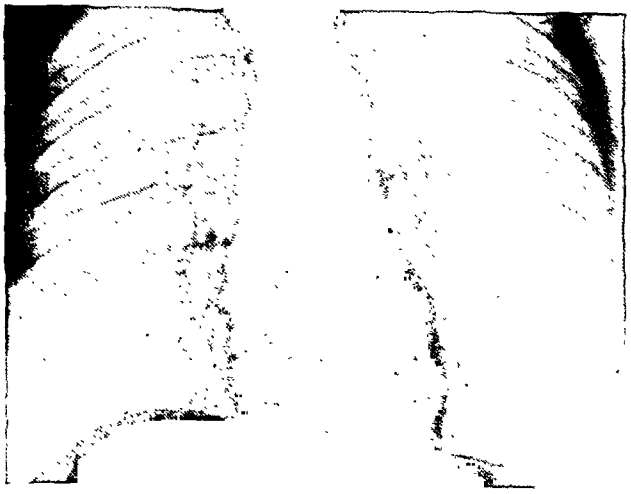

FIG. 1.—CHEST AT END OF NORMAL INSPIRATION. Breath held, but no effort made to force expiration.

FIG. 4.—CHEST AT END OF NORMAL EXPIRATION. Breath held, but no effort made to inspire.

FIG. 2.—CHEST AT END OF NORMAL INSPIRATION (Valsalva's Experiment). Breath held, and extreme effort made to force expiration against obstruction. Pulse could not be detected at wrist, but, when screened, the heart was seen to be making slight movements. Positive intrapleural pressure=75 mm.

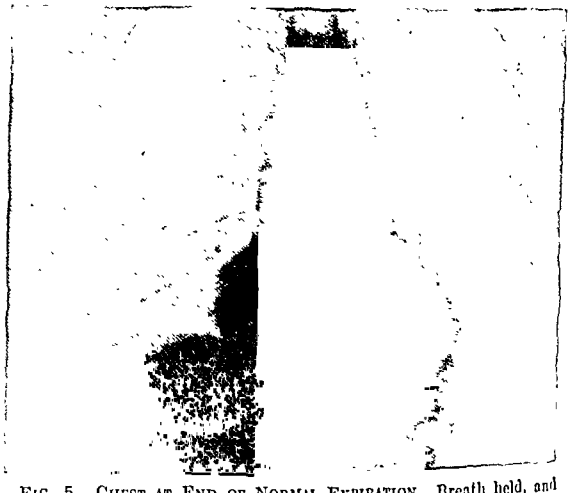

FIG. 5.—CHEST AT END OF NORMAL EXPIRATION. Breath held, and extreme effort made to force expiration against obstruction. Pulse could barely be detected at wrist.

FIG. 3.—CHEST AT END OF NORMAL INSPIRATION. Breath held, and extreme effort made to inspire against obstruction.

FIG. 6.—CHEST AT END OF NORMAL EXPIRATION (Müller's Experiment). Breath held, and extreme effort made to inspire against obstruction. Pulse easily detected at wrist. Heart seen to be beating forcibly when screened. Negative intrapleural pressure=60 mm.

the whole procedure. Fallacious findings will usually be found to be due to faulty technique, or to failure on the part of the patient to follow the instructions. Fallacies due to defective drugs are now practically unknown, but to avoid such a possibility capsules should be bought only from reliable manufacturers. The patient may vomit immediately after taking the capsules; should this occur it is important to inquire whether any of the capsules have been ejected. If pyloric obstruction is present the capsules will dissolve in the stomach no matter how they are coated. The test is said to be contra-indicated in elderly people with low arterial tension and myocarditis, and also in subjects of extensive arterio-sclerosis. While these precautions may be necessary for the intravenous test, the danger of severe reaction from the oral method is practically *nil*.

The following tables have been prepared to show on a percentage basis the confirmation of the *x*-ray findings by operation, and also an analysis of the surgical findings. The cases to which they refer were examined between January, 1926, and October, 1928. There were 47 males and 90 females. The ages were as follows:

Under 20 years	3
20–30 years	13
30–40 years	36
40–50 years	30
50–60 years	40
60–70 years	12
70–80 years	3
Total	137

TABLE I.

Description	No.	Operated.	Correct.	Per Cent.
Normally visualized	48	12	9	75
Faint shadow	19	10	10	100
Late appearance	11	5	5	100
No shadow	40	25	24	96
Stones	19	12	12	100
Total	137	64	60	93
Total cases reported pathological with or without stones	89	62	51	93

TABLE II.—*Analysis of Surgical Findings in Cases Reported Pathological.*

Stones	39
Chronic cholecystitis	8
Adhesions between gall-bladder and colon	1
Adhesions between gall-bladder and duodenum	2
Cirrhosis of liver and chronic cholecystitis	1
Normal gall-bladder	1
Total	52

TABLE III.—*Faint Shadow—10 Cases. Surgical Findings.*

Multiple stones in gall-bladder	5
Stones impacted in cystic duct	1
Adhesions between gall-bladder and colon	1
Adhesions between gall-bladder and duodenum	1
Reported pathological	2
Total	10

TABLE IV.—*Late Appearance—5 Cases. Surgical Findings.*

Adhesion between gall-bladder and duodenum	1
Multiple stones in gall-bladder	3
Cirrhosis of liver, small adherent gall-bladder	1
Total	5

TABLE V.—*No Shadow—25 Cases. Surgical Findings.*

Single large stone in gall-bladder	1
Multiple stones in gall-bladder	13
Multiple stones in gall-bladder and ducts	2
Single stone in common bile duct	1
Chronic cholecystitis	7
Normal gall-bladder	1
Total	25

Of the twelve gall-bladders normally visualized (Table I) upon which operations were performed it will be noted that the *x*-ray findings were incorrect in three cases. One had a malignant liver, and presumably the disease was not so advanced as to prevent the secretion of the bile-stained dye and the filling of the gall-bladder. The gall-bladder itself was not directly involved. In the other two cases single stones were found in the gall-bladder. These were probably stones of intermediate density (to which type I have already referred), not translucent enough to cast a negative shadow and not sufficiently opaque to cast a positive shadow. Of the twenty-five "no shadow" cases which came to operation, in only one were the *x*-ray findings not verified. I cannot explain the cause of this failure. The patient was a hospital case, and may have taken food before the first radiograph. It is of interest also to note that in all those cases presenting faint shadows, or in which the shadow was late in appearing, which were submitted to operation, the *x*-ray findings were verified. This was contrary to what I had expected. In the past my reports upon these cases were made with very great caution, but the result of this study has considerably increased my confidence in the value of these signs. In all operated cases in which stones were visualized, stones were found, but in Table II it will be seen that of all cases reported pathological stones were found in 39, while in only 12 of these were stones demonstrated radiologically. That is to say, 69.3 per cent. of the stones did not cast definite shadows, either negative or positive, which could be recognized as stones.

Conclusions.

1. The oral method of carrying out the Graham-Cole test is reliable and is capable of giving a correct indication as to whether the gall-bladder is normal or pathological in 93 per cent. of cases.

2. Except in the case of visualized stones it is not possible by means of this test to give a precise diagnosis. Different surgical conditions will produce similar *x*-ray appearances, and therefore in the "no shadow, faint shadow, and late appearance cases" one is only justified in saying that the gall-bladder is pathological.

3. The success of the method depends upon the most careful attention to details in preparation and to correct radiographic technique.

THE EFFECT OF OBSTRUCTED RESPIRATION ON HEART AND LUNGS:

ITS CLINICAL IMPORTANCE IN RADIOGRAPHY.

BY

GUY P. CROWDEN, M.Sc., M.R.C.S., L.R.C.P.
(Institute of Physiology, University College),

AND

H. A. HARRIS, M.B., B.S., D.Sc.
(Institute of Anatomy, University College, and Medical Unit, University College Hospital).

(*With Special Plate.*)

DURING normal systole the heart changes its shape, size, and position, and pumps an average charge of 75 c.cm. of blood from each of the ventricles into the aorta and pulmonary artery. The discharge of blood into the pulmonary artery disturbs the size, shape, and position of the pulmonary vascular tree, and the pulmonary arteries are straightened in systole and relatively curved in diastole. Since the pulse wave in the pulmonary arteries is estimated to travel at three to six metres a second, it reaches the periphery of the lung in an interval of time which is probably not greater than one-sixtieth of a second. This indicates that the ideal radiogram of the chest requires an exposure of about one-hundredth to one-sixtieth of a second, so as to eliminate the effect of the propagation of the pulse wave along the arteries. The possibility of obtaining radiograms from such a brief exposure is entirely outside the range of most hospital *x*-ray equipments. In the majority of cases, with the existing apparatus, an exposure of less than half a second cannot be employed with any measure of success.

Apart from the movements in the lung vessels due to each cardiac cycle, the slower rhythm of inspiration and expiration also leads to a change in size, shape, and position of the bronchial and vascular tree. In inspiration the trachea, bronchi, and bronchioles become lengthened and revert to their original length in expiration. The movements of the respiratory apparatus in the subject who is being screened can be voluntarily controlled to some extent, but the involuntary cardiac movements cannot be controlled except to a slight extent by the voluntary control of respiration or by the voluntary assumption of the extreme erect attitude of attention. It is essential that all routine radiograms of the chest should be taken under strictly defined standard conditions in a particular phase of inspiration or expiration, and, if possible, in a particular phase of the cardiac cycle. So far one of the most successful attempts in this direction has been made by MacPhedran and Weyl[1] of the Henry Phipps Institute, Philadelphia. They have applied a tambour to the area of carotid pulsation on the neck of the patient, and the excursions of the tambour are employed to deflect a beam of powerful light on to a photo-electric cell of the vacuum type. This in turn is connected by way of an amplifier to a relay which operates the switch of the x-ray tube. In this manner a radiogram can be taken not only in a given phase of respiration but also in a given phase of the cardiac cycle with an exposure of one-twentieth of a second, and a minimum lag of one-twenty-fifth of a second between cardiac systole and the actual commencement of the exposure.

Both in the routine teaching of the normal radiographic appearance of the chest to students of anatomy and physiology, and in observing the varied symptoms of patients who have been screened or radiographed in the erect attitude, it has been noted that the subject may exhibit symptoms of distress ranging from dizziness to fainting. It was evident that in certain cases the respiratory mechanism was influencing the circulation of the blood to an inordinate extent. On viewing two radiograms of the chest of a certain subject it was observed that there was considerable variation in the appearance of the root shadows, and it was thought that this might be due to some alteration in the amount of blood present in the heart and lungs at the moment the photographs were taken. It was therefore determined to vary the amount of blood reaching the heart and lungs by repeating the classical experiments of Valsalva (1740) and Johannes Müller (1838) and to take radiographic records of the chest under the varying conditions obtainable. In Valsalva's experiment, after a deep inspiration is taken, the glottis is immediately closed and a strenuous and prolonged expiratory effort is made, but without allowing the air to escape. Such pressure is exerted on the heart and intrathoracic vessels that the movements and flow of blood are almost entirely arrested. "Pronounced swelling of the veins, visible principally in those of the neck and face, evacuation of the vessels in the pulmonary system, and surcharge of the systemic circulation, cessation of cardiac sounds, and disappearance of the arterial pulse can all be witnessed" according to Luciani.[2] In Müller's experiment the glottis is closed at the end of expiration and an attempt is made forcibly to inspire. "The heart and all the intrathoracic vessels fill to such an extent that the arterial pulsations cease owing to the surcharge of the lesser, and comparative evacuation of the greater circulation" (Luciani). These experiments are not devoid of risk in old age and in patients suffering from cardio-vascular disease.

Standard radiograms of the chest of a healthy male, aged 33, of hypersthenic build, were taken under the varied conditions of intrapleural pressure which are produced in the experiments of Valsalva and Müller. The pressure of the air in the lungs was recorded by means of a mercury manometer connected to a tube in the mouth of the subject, care being taken to keep the glottis open, the nose being clipped, during the reading of the pressure. The standard conditions for the radiograms were a tube distance of two metres to minimize distortion, Coolidge tube of universal type, and an exposure of half a second at 110 kilo-volts, the patient standing erect with the screen immediately in front of him. Such a series of radiograms demonstrates the effect of changes of pressure in the pleural cavity on the volume of blood reaching the heart, and the variations in the size of the cardiac shadow within the physiological limits of respiration.

Fig. 1 shows the chest at the end of normal inspiration. The pressure of the air in the lungs is in equilibrium with that of the atmosphere. Assuming that the pressure due to the elasticity of the lung substance is 15 mm., the intrapleural pressure is 745 mm., so that there is a virtual negative pressure in the pleural cavity of (760−745)=15 mm.

Fig. 2 shows the chest at the end of normal inspiration, when an extreme effort is made to force expiration against obstruction, as in Valsalva's classical experiment. The radial pulse could not be detected, though the heart could be seen beating feebly on the fluoroscopic screen. The pressure of the air in the lungs rises to 850 mm. Allowing 15 mm. for the elasticity of the lung substance, the intrapleural pressure is 835 mm., or a positive pressure of (835−760)=75 mm. This increase of the intrapleural pressure prevents the return of venous blood to the heart from the great veins of the neck and abdomen. The result is clearly indicated by the marked decrease in the size of the cardiac shadow and the extent of uncovering of the lung roots. On ceasing the effort at forced expiration the face of the subject was suffused with blood, and a sudden sensation of dizziness developed. It must be repeated that this experiment of Valsalva is not without its dangers in the unfit.

Fig. 3 shows the chest at the end of normal inspiration, when the subject attempts to inspire still further against obstruction. The pressure of air in the lungs is reduced to 680 mm. Allowing 15 mm. for the elasticity of the lung substance, the intrapleural pressure is 665 mm., or a negative pressure of (760−665)=95 mm. The flow of blood into the heart is suddenly increased, as shown by the size of the cardiac shadow, which is greater than that shown in Fig. 1, and still greater than that in Fig. 2. The increased density at the lung root in this experiment is marked, and may easily lead to errors in radiographic reports in relation to conditions at the hilum. The increased density of the shadow is due to marked engorgement of the pulmonary vessels.

In addition to three experiments with radiographic records (Figs. 1–3) at the end of inspiration, three corresponding experiments were performed at the end of expiration. Fig. 4 shows the chest at the end of normal expiration. The pressure of the air in the lungs is 760 mm. The pressure exerted on the contained air by virtue of the elasticity of the uninflated lung is approximately 5 mm., so that the pressure within the pleural cavity is 755 mm., or a negative pressure of (760−755)=5 mm. Fig. 5 shows the chest at the end of normal expiration when the subject forces expiration still further against obstruction, as in "bearing down" or "straining at stool." The radial pulse could barely be detected at the wrist. The pressure of the air in the lungs was 835 mm., the pressure within the pleural cavity, allowing 5 mm. for the elasticity of the lung substance, was 830 mm. This yields a positive pressure of (830−760)=70 mm. The diminution in the volume of blood reaching the heart, as evidenced by the reduced size of the cardiac shadow, is most marked. The decrease in the size of the cardiac shadow is not so marked as in Valsalva's experiment (Fig. 2). The differences between Figs. 4 and 5 are of the same kind, but not of the same degree, as those between Figs. 1 and 2.

Fig. 6 was taken at the end of normal expiration, the subject making an effort to inspire against obstruction, as in Müller's experiment. The pressure of the air in the lungs is 675 mm. The intrapleural pressure is 670 mm., or a negative pressure of (760−670)=90 mm. The size of the heart is distinctly greater than in Fig. 5, and in contrast to Fig. 2, with the minimal cardiac inflow, is most marked. The heart in Fig. 6 is receiving the maximal inflow of blood that can be brought about by voluntary change of intrapleural pressure. The clinical picture corresponds closely to that seen in the attempt at inspiration against obstruction after a series of expiratory coughs in whooping-cough or in some phases of the dyspnœa of asthma. The density of the shadow of the lung roots should be compared with that in Fig. 2, when the cardiac inflow was at the minimum. The subjective disturbance in this experiment of Müller is not so marked or so easily produced as that in Valsalva's experiment.

The Significance of the Dead Spaces of the Chest.

As in the neck, so in the chest, certain spaces of great pathological significance are never seen in the routine dissection of the formalin-fixed cadaver. The textbook diagrams of fascial planes in the neck and of lines of pleural reflection in the chest do not emphasize the existence of those "dead spaces" filled with loose areolar tissue

which permit considerable distension of certain viscera, such as the pharynx and oesophagus, and of extreme distension of the veins in any condition involving severe physical effort or pathological venous congestion. In the thorax it is important to realize the extent of the fascial spaces in the posterior mediastinum and in relation to the lung roots, for those "dead spaces" not only allow room for expansion of engorged veins, but also determine the direction of expansion and spread of enlarged lymphatic glands and mediastinal tumours. The root of the left lung is almost encircled by the relatively resistant arch of the aorta, with a marked condensation in the surrounding connective tissue, whereas the root of the right lung is almost encircled by the dilatable vena azygos major and superior vena cava. The enlargement of glands, whether of the carinate group at the bifurcation of the trachea, or of those in the hilum of the right or left lung, is therefore directed towards the right side of the thorax. It is this tendency for the glands to enlarge on the right side which accounts for the phenomenon of right-sided paravertebral dullness, which has been so rightly emphasized by Riviere.[3] Similarly the conduction of the whispered voice from the third to the fifth dorsal spine on the right side, as described by d'Espine, is another manifestation of the enlargement of the glands to the right. Opie has emphasized that the common calcium-bearing glandular lesions, distinguished by the deposition of calcium salts, are right-sided irrespective of the side in which the pulmonary and intrapulmonary glandular lesions occur. In fatal infantile disease the calcium-bearing mass of glands often extends as far as the right side of the bodies of the vertebrae. Opie[4] has also stressed that the commonest demonstrable site of calcification, either radiographically or at necropsy, is in that lymph node which sits to the right of the trachea just above the bifurcation and above the arch of the vena azygos major.

Furthermore, the mediastinal pleura of the right side, above the level of the lung root, covers over a dead space extending from the superior vena cava anteriorly to the trachea and oesophagus medially, the right vagus lying somewhat freely therein. Enlarged glands in this area are frequently seen, and it is the perifibrosis thereof which so frequently leads to a strange "bruit de diable" over the right apex and neck, and renders the clinical signs in this area equivocal. The lowest gland in this space, just above the arch of the vena azygos major, is the one which most frequently displays a lesion, as mentioned above.

In order to obtain an instructive radiogram of the chest by freeing the right and left lung root from the shadow of the heart and great veins, it is essential to take the radiogram in that phase of respiration which fills the lungs with air and at the same time empties the heart of blood to the maximal extent. This is best accomplished by pinching the nostrils of the patient at the end of inspiration, either digitally or by a clip, and asking him to expire forcibly (Fig. 2), as in Valsalva's experiment. If the condition of the patient is such that Valsalva's experiment is dangerous, then the radiogram should be taken at the end of expiration, with forced expiration against obstruction, as in "bearing down" (Fig. 5). The information thus gained adds greatly to the value of the radiogram, and saves the expense of two or more oblique radiograms. Although with routine work with a Coolidge tube it is difficult to determine the size of those glands at the hilum which are enlarged but uncalcified, it should be noted that the gas tube often gives information of the degree of enlargement of both the calcified and uncalcified glands. This is well seen during and after an attack of measles or whooping-cough.

The repetition of the classical experiments of Valsalva and Müller, with the visible aid afforded by the *x*-ray screen and photography, clearly demonstrates the wide variation in appearance of the thorax in the same individual, and shows the need for further standardization in routine radiography of the chest. A given individual under different phases of respiration may simulate "cor bovinum" or "cor pendulosum." A brief study of the six radiograms presented indicates the need for the reconsideration of many of the terms used by the radiologist. Such terms as "dilated heart," "peribronchial fibrosis," and "increased hilum shadows" may have to be abandoned.

With the growth of knowledge accurate diagnosis is coming to depend, even in greater measure than it has in the past, on considerations of exact anatomy and physiology applied with understanding to the concrete pathological problem presented by each individual patient.

THE DEEP SUBMAXILLARY LYMPH GLANDS.

BY

D. M. BLAIR, M.B., CH.B.,

PROFESSOR OF ANATOMY, UNIVERSITY OF LONDON, KING'S COLLEGE.

THE submaxillary lymph glands have for long been recognized as a chain of glands occupying the groove between the lower border of the mandible and the superficial surface of the submaxillary salivary gland. The number of glands is variably given, but three large ones are considered fairly constant. The biggest of these is usually in the centre of the chain, lying below the facial artery as it turns upwards on to the mandible. Other glands, placed one anteriorly and one posteriorly to this, complete the trio. There may be additional smaller glands in the chain, or one of the main three may be absent, particularly the posterior one. These glands lie beneath the superficial layer of deep cervical fascia, but outside the capsule of the submaxillary gland. Occasionally one finds mentioned deeper lymph glands beneath the salivary gland or inside its capsule, but no very exact account of observations on which such statements are based can readily be found.

It is well-known that lymph glands are to be found actually embedded in the substance of the parotid gland. So intimate is the relationship between the two that, as Neisse demonstrated, salivary acini are to be found invading the interior of some of these intraparotid lymph glands. It does not yet seem to have been determined whether such interrelations exist between the submaxillary salivary and lymphatic glands, although Poirier and Cunéo make the positive statement that "contrary to what we have noticed in the case of the parotid, there do not appear to be any lymphatic glands included in the submaxillary salivary gland."

In 1903 von Brunn addressed himself to this problem. He specially wished to find out if metastases in the submaxillary salivary gland occurring in cases of labial or lingual carcinoma were to be explained by the presence of lymph glands inside the salivary gland. He gives, as surgeons will do, a black list of the standard anatomy textbooks of his time, which threw no light upon his problem. Even the voluminous Sappey failed him. Turning to more specialized works, mostly studies of the lymphatic drainage of the tongue, he found that although one or two investigators who had injected the lymphatics of this region did not find any deep submaxillary glands, others made passing mention of small glands inside the submaxillary gland capsule or even enveloped by the gland. But these last did not give satisfactory accounts of work on which their statements were based. Von Brunn, therefore, himself examined 61 submaxillary salivary glands, which he cut into sections 2 or 3 mm. thick. The sections were examined unstained, and his drawings at any rate are only naked-eye views. Of the glands, 15 were removed at operation from 9 cases of cancer of the lower lip or tongue. One or two of those contained carcinomatous nodules, but there were lymph glands in none. The remaining 46 submaxillary glands were taken from 23 subjects of all ages, dead of conditions other than disease of this region. In two only, from different individuals, were lymph glands found. In each case a single small gland was seen embedded in connective tissue prolonged into the submaxillary gland as

a thick, vertical septum from around the facial artery ascending in its groove on the posterior pole of the salivary gland. This position von Brunn characterized as clinically, though not anatomically, in the gland substance.

In 1907 Bartels, in a specially successful injection of the lymphatic vessels draining the tongue in a newborn child, noted a small lymph gland injected lying close to the submaxillary gland. He described it as lying under the capsule of the submaxillary gland, and designated it as a "parasubmaxillary" gland similar to those described by von Brunn. But he stated that it was separated from the salivary gland by the facial vein, which deeply furrowed the posterior end of the latter, and from his illustration it might quite well be regarded as a variant of a member of the superficial submaxillary chain which is sometimes found lying below the others on the anterior facial vein as it crosses the superficial aspect of the salivary gland. The little gland was connected by a lymphatic vessel with the middle gland of the main submaxillary chain, which had been injected from the lymphatics passing from the tongue. Bartels did not trace any direct lymphatic from the tongue to this parasubmaxillary gland; as it was unconnected with any other gland it was presumably injected by retrograde flow from the main submaxillary lymph gland just mentioned.

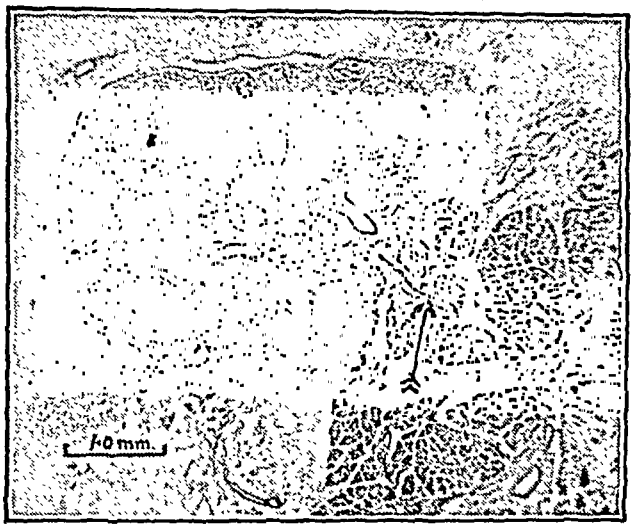

FIG. 1.—Low power photomicrograph of deep submaxillary lymph gland. Note salivary tissue (on the right) invading hilum. The arrow points to the union of the duct draining the invading acini with another from the adjacent salivary lobule.

In his volume on the lymphatic system in Bardeleben's textbook, Bartels classifies the deep glands such as those described by von Brunn and himself, as well as those more casually mentioned by others under the capsule of the submaxillary gland, as "paramandibular" glands, distinct from the "mandibular" glands. (In this work Bartels corrects the term "submaxillary" of the B.N.A. into "mandibular.")

If, as is probable, these intracapsular lymph glands have only a localized drainage from the salivary gland itself, one cannot be certain of revealing them by injection methods. It seemed that the only sure way to determine their presence and exact relation to the salivary gland would be to examine microscopically stained serial sections of the latter. This was therefore done with four submaxillary salivary glands taken from young children.

Two of those showed no trace of any lymph gland directly related to them. In another a lymph gland of typical structure was found closely applied to its posterior pole beneath the salivary gland capsule. It was directly applied to the subjacent salivary acini which at the hilum of the lymph gland mingled with the issuing lymphatic vessels. Beyond this on one side a thin process of the lymph gland was prolonged for some distance under the capsule over a salivary lobule. In the remaining submaxillary gland a lymph gland was found under the capsule presenting still closer relations to the salivary tissue (Fig. 1). Salivary acini were seen invading the hilum of the lymph gland and lying scattered throughout its medulla, abutting on the cortex in places (Fig. 2). The invading acini were drained by a duct which passed out of the lymph gland to join another draining the adjacent part of the submaxillary gland. This recalls the finding of Neisse in the parotid gland.

Thus there do exist, in some cases but not in all, deep submaxillary lymph glands inside the capsule of the submaxillary salivary gland, and directly related to the salivary acini. There seems to be no good reason for putting these deep glands, as Bartels has done, in a separate group from the more constantly found and more superficially placed submaxillary lymph glands. As in the case of the parotid salivary and lymph glands, all the lymph glands regionally associated with the submaxillary salivary gland may be classed together as submaxillary lymph glands. The main glands of this group, constantly present in varying numbers, are superficially situated under the deep fascia and external to the submaxillary gland capsule. Smaller and deeper members of the group are sometimes found embedded in the capsule (as those described by von Brunn) or inside the capsule in direct relation to the salivary tissue (as those I have now described).

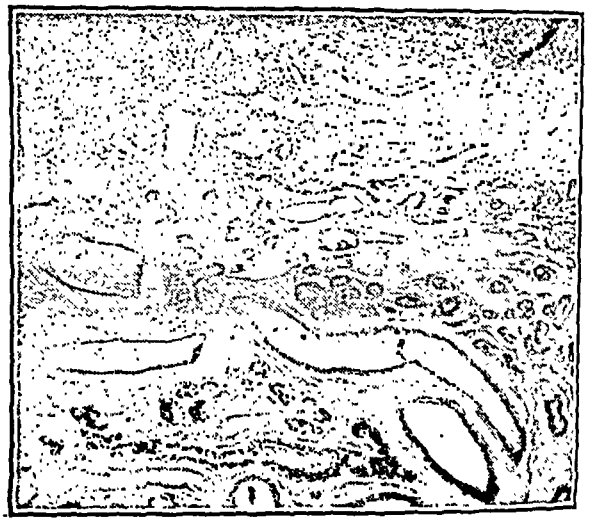

FIG. 2.—Higher power view of another section of the same lymph gland as in Fig. 1, showing adjoining cortical zone (above) and medullary zone (below). The medullary portion is studded with salivary acini; a salivary ductule is running horizontally close to the lower edge of figure.

The practical importance of the occasional presence of these deep lymph glands is twofold. Surgically, one cannot be sure of removing all submaxillary lymph glands present without removing also the salivary gland, as is the usual practice. Pathologically, these deep glands may be responsible for some occurrences of cancerous metastases in the salivary gland, and may be the real seat of the rare cases of apparently primary tuberculosis in the submaxillary gland.

In examining the sections used in this investigation one was struck by the comparative absence of lymphoid tissue round the submaxillary ducts. Where present at all this was confined to very small collections of lymphocytes around the smaller, but not the smallest, ducts. Rawitz has described masses of lymphoid tissue visible to the naked eye in stained sections of submaxillary gland in *Cercopithecus sabeus*. These masses surrounded the smaller ducts and were devoid of all structural appearances resembling those of organized lymph glands. Rawitz claimed to have excluded the possibility of these masses being of inflammatory nature. No such appearances were seen in the human glands here studied.

My acknowledgements are due to Professor Evatt, of the Royal College of Surgeons, Dublin, who kindly supplied the submaxillary glands examined, and to my laboratory assistant Mr. Weston, who undertook the laborious preparation of the sections.

SPONTANEOUS AND ARTIFICIAL PNEUMOTHORAX.*

BY

ALBERT RAMSBOTTOM, *M.C.*, M.D., F.R.C.P.,

PROFESSOR OF CLINICAL MEDICINE, MANCHESTER UNIVERSITY; HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

PNEUMOTHORAX, or the presence of air in the pleural cavity, is, I think, a subject worthy of our consideration for two reasons: in the first place, because the occurrence of spontaneous pneumothorax, though perhaps rare, is one of our medical urgencies, and therefore cannot be considered unimportant; and in the second place, because the induction of artificial pneumothorax has now become an established method of treatment in certain cases of pulmonary tuberculosis. In fact, Sir James Kingston Fowler has said that "the induction of artificial pneumothorax is the only advance in the treatment of pulmonary tuberculosis since the introduction of sanatorium treatment as carried out at Nordrach."

Source of the Air.

Normally the pleural cavity, save for a little lubricating fluid, is a vacuum. Air may reach it:

(*a*) From the atmosphere, the result of a penetrating wound of the chest wall which perforates the parietal pleura. Apart from pneumothorax artificially induced, such instances are but seldom met with, though I have known it to be caused in a man by a deliberate stab in his side with a hat-pin during an altercation with his wife.

(*b*) From the lungs, the result of the rupturing of a tuberculous focus, usually a cavity, or the bursting of an emphysematous bulla, or laceration of the lung by an adhesion under strain.

(*c*) From a hollow viscus, the result of a foreign body ulcerating through the wall of the œsophagus, or occasionally by a peptic ulcer perforating the diaphragm.

Of these, the lung is pre-eminently the source of air in spontaneous pneumothorax, and the preponderating cause is the rupture of a tuberculous focus, usually a tuberculous cavity. Should such a cavity be small and its contents not highly infected with pyogenic organisms, then hydropneumothorax will result, whereas the rupture of a large cavity containing a quantity of highly infected material will give rise to pyo-pneumothorax, which is of the two the much more common complication. Simple pneumothorax, unaccompanied by fluid, may be due to laceration of lung by a pleural adhesion of tuberculous origin, or, as suggested by Parkes Weber,[1] to the rupture of a "cicatricial" bulla, the result of a previous minute tuberculous focus and adherent to the parietal pleura, the adhesion keeping the rupture open for a time. In some of these latter cases, however, hydro-pneumothorax may result owing to the cicatricial bulla containing a caseous remnant.

RECURRENT PNEUMOTHORAX.

In rare instances it happens that this accident occurs several times at varying intervals in the same patient. A case has been reported in which as many as eleven attacks have occurred. Personally I have seen but one case in which recurrent spontaneous pneumothorax has occurred, and that was the case of a man, aged 30, who gave a history of three attacks. The first was in December, 1922, and affected the left side. The other two attacks were both right-sided, and occurred in June, 1923, and March, 1928, respectively. The man was of athletic build, and examination of his chest when I saw him on May 18th, 1928, revealed no evidence either clinical or radiological of pulmonary disease. Moreover, he stated that each winter between the two last attacks he had played Rugby football regularly.

With few exceptions spontaneous pneumothorax makes its appearance in these cases like a "bolt from the blue" in a patient in whom no pulmonary disease was suspected, and in whom no pulmonary disease, even after the attack, can be detected by any known method. On the whole, the prognosis in these cases is good, whereas the incidence of pneumothorax in cases of known pulmonary tuberculosis is of extreme gravity. It seems probable that the explanation offered for recurring spontaneous pneumothorax is also the explanation of many cases of spontaneous pneumothorax attributed to the rupture of an emphysematous bulla, for it would appear that a bulla such as is seen on the margin of a lung in emphysema would, on rupturing, collapse, and prevent the escape of air in a quantity sufficient to produce an appreciable pneumothorax. Furthermore, emphysema is so common that were it a potent etiological factor pneumothorax might be expected to be met with more frequently. That adhesions could play a part in maintaining the patency of the aperture is unlikely, for adhesions in emphysema are conspicuous by their absence. It may be that pneumothorax arises only in those cases of emphysema where the ruptured bulla is in free communication with a bronchus large enough, and in consequence rigid enough, to resist collapse.

Pneumothorax has been classified into open, closed, and valvular, according as the aperture in the lung remains open, or is so small that it closes almost immediately, or is valvular, which no doubt explains the majority of cases. *In these cases air enters the pleural cavity during inspiration*, and, owing to the opening being valvular, cannot escape during expiration; thus the imprisoned air gradually accumulates until it exerts a pressure within the pleural cavity sufficient to close the valvular opening even during inspiration. If this state continues long enough the valvular opening will heal, and the air will ultimately be absorbed. Should, however, absorption of air take place before the valvular opening has healed it will burst open and allow more air to escape into the pleural cavity. This, according to Fishberg,[2] is the explanation of the return of dyspnœa in some cases of pneumothorax after paracentesis.

Symptoms.

The onset of pneumothorax in the majority of instances is abrupt. The patient is suddenly seized with intense pain in the affected side, has urgent dyspnœa, and all the symptoms of collapse. In some cases, however, the onset is anything but acute; in fact, the presence of pneumothorax may be unsuspected until discovered in the course of routine examination. The acuteness of the symptoms at the onset depends upon the functioning ability of the affected lung immediately preceding the escape of air into the pleural cavity. If the tuberculous infection is limited in extent so that the lung is for the most part functioning when the rupture occurs, then at the moment of rupture the symptoms will be intense, because a functioning lung has suddenly been put out of action; but if, as is sometimes the case, the whole lung is extensively involved with tuberculous infection so that prior to the rupture it has little or no function, then at the time of the rupture the symptoms will hardly be perceptible.

Physical Signs.

The affected side, which is immobile, is enlarged and the intercostal spaces may bulge, as opposed to what occurs in simple pleural effusion, when, as pointed out by Hale-White,[3] the affected side is often seen to be actually smaller than the sound side. The percussion note is hyperresonant, or even tympanitic, and the breath sounds over it are diminished in intensity. A cough, or even spoken words as heard over the affected side of the chest, and even rales should they be present, assume a peculiar metallic quality. It is in this condition also that the so-called "coin sound" is typically heard. One coin is placed flat on the upper part of the chest wall in front on the affected side, and an assistant taps it with another coin while auscultation is performed behind, with the stethoscope on the back at a point opposite the coin. With each tap of the coins a bell-like tinkle is heard through the stethoscope. If, in addition to air, there be fluid in the pleural cavity, then that fluid is found to shift with altered positions of the patient, so that an area which emits a dull note on percussion with the patient sitting up may become resonant on his lying flat. Moreover, with the patient in the erect posture, as is well demonstrated in radiograms, the upper limit of the fluid is a horizontal line, whereas in uncomplicated pleural effusion the upper limit of the fluid is represented by a curved line with its convexity upwards and its

* An address delivered before the North Lancashire and South Westmorland Branch of the British Medical Association on December 5th, 1928.

highest point in the axillary line. Again, when both air and fluid are present in the pleural cavity, a splashing sound will be produced on shaking the patient. The displacement of the heart in pneumothorax is frequently very great, for the entry of air into the pleural cavity destroys the cohesive property of the pleura by separating their two opposing surfaces so that the lung collapses, thus leaving unopposed the normal negative pressure set up by the other lung, and in consequence the heart is pulled over towards the sound side.

Treatment.

The acute symptoms at the onset should be relieved by a hypodermic injection of morphine and the application of a hot fomentation to the side. In many cases this is sufficient, and in three or four weeks the air will have been absorbed. In other cases, however, it may be necessary to tap the air in the pleural cavity, and this may have to be repeated three or four times in the first twenty-four hours. In such cases Fishberg recommends the injection of a quantity of air into the pleural cavity, on the assumption that the rise of pressure so caused will be sufficient to keep the perforation in the lung closed long enough to enable it to heal. In hydropneumothorax the same conservative plan is adopted as in the treatment of a simple pleural effusion. No mechanical intervention is undertaken for some three weeks, unless rendered necessary at an earlier date by the appearance of the signs of positive intrathoracic pressure. At the end of this time, if there are no indications of absorption, air is removed, and only after this has proved inadequate is fluid withdrawn. In pyo-pneumothorax the pus is withdrawn as soon as diagnosed, preferably by repeated aspirations in tuberculous cases.

ARTIFICIAL PNEUMOTHORAX.

The treatment of pulmonary diseases by the induction of artificial pneumothorax was first suggested by Carson, a Liverpool physiologist, about 1822, but it is only in recent times that the method has been employed on an extensive scale. It is now recognized as a valuable therapeutic measure in properly selected cases of pulmonary tuberculosis, in severe cases of haemoptysis, and to replace a pleural effusion or "tuberculous empyema." Less frequently it is employed in the treatment of bronchiectasis and pulmonary abscess.

In regard to pulmonary tuberculosis, all are agreed that the most suitable type of case for pneumothorax therapy is the one in which the lesion is unilateral and unaccompanied by firm adhesions, but opinions differ in regard to the most suitable stage in the course of the disease in which to employ the treatment. Some authorities advocate pneumothorax therapy in the early stages of unilateral lesions, on the grounds that the chances of the disease becoming bilateral are thereby diminished, that there is less likelihood of meeting with firm adhesions, and that the more local the disease the more chance is there of the lung refunctioning after compression. Others, however, prefer to wait until residence in a sanatorium has been given a trial before resorting to artificial pneumothorax. Personally, I adopt the latter course, and only consider the induction of artificial pneumothorax if, at the end of six months' residence at a sanatorium, there is no improvement in the patient's condition. The effect of sanatorium treatment in these early cases is, in my experience, so beneficial that the number of cases that will require the induction of pneumothorax is very small. The value of pneumothorax therapy lies more in the fact that it may prove beneficial in those cases which do not respond to ordinary sanatorium treatment, rather than in its being applicable to great numbers.

It is sometimes employed with success in cases in which both lungs are involved, provided that the second lung is but slightly affected, but such a procedure is not without risk, for it may, and does sometimes, lead to rapid extension of the disease in the uncollapsed lung.

Method of Induction.

To the method of induction of artificial pneumothorax I do not propose to refer, for the technique can only be learnt from an actual demonstration. An initial 300 c.cm. of air is introduced, not with the object of causing collapse of the lung, but of producing a cavity of reasonable size which can be enlarged by subsequent refills. The first refill is usually given the next day, and the second about two days after the first. Afterwards the refills may be repeated at intervals of three days, then at four or five, the intrapleural pressure being gradually raised each time until at the end of two or three weeks efficient collapse has, as a rule, been obtained. In these refills the amount of air given varies between 600 and 900 c.cm. If more than this is required it is safer to give the refills at more frequent intervals than to put in a larger quantity at one time. It then remains to space and adjust the refills so as to prevent the lung from expanding again. This can only be determined by a careful watch on the temperature chart, the patient's weight, and the signs, symptoms, and *x*-ray appearances in each case. Frequent *x*-ray examination is the best way of ascertaining the amount of collapse. In cases of haemoptysis, where rapid compression of the lung is desired, a larger quantity of air than is usual in the ordinary case of pulmonary tuberculosis may be given.

Once the lung has collapsed efficiently it is inadvisable to allow it to expand under two years, and even at the end of that time, if on expansion there is a return of symptoms of active pulmonary tuberculosis, further refills must be given. After such efficient collapse monthly refills are usually sufficient to maintain it.

The presence of laryngeal tuberculosis is no bar to the employment of artificial pneumothorax, but its induction is contraindicated when there is extensive and active disease in both lungs, or when there is extensive tuberculous disease elsewhere; also in cases complicated with heart disease, diabetes, asthma, bronchitis, and emphysema, and in old people and persons of a highly nervous temperament.

The main principle underlying the therapeutic value of artificial pneumothorax is rest. Rest is essential to the healing of any wound, and collapse of the lung affords such rest by annulling the respiratory excursions. Moreover, by relieving the state of tension in which lung tissue normally exists, it promotes healing by allowing cavities to collapse, with consequent apposition of their walls and ejection of their toxic and infective contents. Again, collapse of the lung induces a venous and lymphatic stasis in the lung, and thus promotes the formation of fibrous tissue. The effect of such stasis is also to retard the absorption of toxic products into the general blood stream and to impede the escape of tubercle bacilli into the lymph stream, thus tending to localize the lesion.

Furthermore, it is suggested by Goebel[4] that the tubercle bacillus, being an aerobic micro-organism, requires a plentiful supply of oxygen, and therefore does not thrive so well in a lung which is collapsed owing to obliteration of the pulmonary capillaries.

THE MENTAL ASPECT OF EPIDEMIC ENCEPHALITIS.*

BY

S. BARTON HALL, M.D.,

HONORARY CONSULTING PSYCHOTHERAPIST, WATERLOO AND DISTRICT GENERAL HOSPITAL; HONORARY PHYSICIAN, NEW PSYCHOTHERAPEUTIC CLINIC, LIVERPOOL.

Occurrence.

MENTAL symptoms were found to have occurred in a high proportion of cases. Thus, of 113 patients, mental symptoms were noted in 92, at either acute or chronic stage. In view of the variation of symptoms and their relation to the age of the patient the cases were analysed with special reference to the age factor. For this purpose the patients were divided into two groups: (1) children and adolescents up to the age of 18 years inclusive, and (2) patients aged 19 years and above. One patient from each group failed to survive to the chronic stage.

* Being the abstract of a paper which was read before the Liverpool Medical Institution on December 13th, 1928.

Children and young people showed a rather greater liability to mental affection than did the patients of adult years. Of the 113 patients, 47 were of Group 1; 42 of these (that is, 89.4 per cent.) showed mental symptoms, and of the 5 patients not so affected none were under the age of 15 years. On the other hand, from the 66 adult cases mental affection was noted in 44 (that is, 66.6 per cent.). In Group 1, therefore, mental symptoms occurred with greater frequency than in Group 2, and were the rule in all cases under the age of 15 years.

Mental Symptoms in Epidemic Encephalitis: Occurrence of Symptoms According to Age Groups.

Type of Case or Symptom.	Group I. Children and Adolescents (aged 1-18 inc.).	Group II. Adults (aged 19 and over).
ACUTE STAGE:		
Total cases of epidemic encephalitis ...	47	66
Cases showing mental symptoms ...	42 (89.4%)	44 (66.6%)
Acute delirium	27 (77.8% became chronic)	29 (34.4% became chronic)
Sleep disturbance	25	24
Emotional or conduct change	9	4
Psychotic symptoms...	3	5
Catalepsy stupor, etc.	13	13
CHRONIC STAGE:		
Conduct change	21	11
Moral change	12 | 55	0 | 24
Emotional instability	22	13
Psychotic symptoms	5	13
Phobias and psychoneurotic symptoms	4	3
Bradyphrenia	11	13
Nocturnal excitement	12	6

DEGREE OF PERMANENCE.

There appeared, too, to be a greater tendency towards the more permanent type of mental affection among children and adolescents than among adults. Out of 92 cases showing mental symptoms at some stage, a history of acute delirium was given in 56—27 in Group 1, 29 in Group 2. In 21 cases out of 27 (that is, 77.8 per cent.) in Group 1 mental symptoms were noted in the sequel, while of the 29 adult patients only 10 showed a mental sequel (that is, 34.4 per cent.). The degree of mental affection at onset appeared to bear no relation to the symptomatology of the sequel.

PROGNOSIS.

With regard to the general question of prognosis in the case of mental disorder occurring during epidemic encephalitis, it has already been indicated that there is a greater tendency to the more permanent type of mental affection among children and adolescents than among adults. Of the 61 cases in which mental symptoms occurred during the chronic stage, or sequel of the disease, 23 showed gross mental change such as should warrant special care, whether the symptoms consisted of change of conduct, moral change, or states akin to the manic-depressive psychosis or chronic delusional insanity. Of these 23 cases, 16 belonged to Group 1, and while under observation none of the 16 recovered a normal state of mind. On the other hand, from the 7 cases belonging to Group 2, which were observed over the same period of time, several of whom were certified, 5 showed a complete return to sanity. It would seem, therefore, that the prognosis with regard to mental affection, other than delirium at onset, which occurs during childhood or adolescence, is extremely bad. On the other hand, in adults, even when the symptoms are of gross mental disorder, and might indicate a bad prognosis where the case is one of pure psychosis, the prognosis is relatively good, since in patients in whom the encephalitic mental state resembles psychotic disorder of an extremely chronic type complete recovery frequently occurs.

THE AGE FACTOR IN SYMPTOMATOLOGY.

The dependence of mental symptomatology on the age of the patient, so often recorded in the past, was well illustrated in the present series. The case records were analysed to determine the incidence of the following groups of symptoms: in the acute stage from delirium, neurosis, emotional instability, change in conduct, moral change, disorder of sleep, nocturnal excitement, psychotic symptoms, and evidence of katatonia, catalepsy, or stupor; and in the chronic stage for bradyphrenia and euphoria in addition to the above.

During the acute stage the symptomatology of the two age groups was very similar, with the exception that patients who exhibited marked emotional instability and change of conduct as the chief feature of their acute attack were more common in Group 1, comprising children and young adults.

In the sequel the differences between the two groups were very much more marked. The mental symptomatology of Group 1 was characterized by change in conduct, moral change, emotional change, and nocturnal excitement. In adults, on the other hand, not only was the tendency to mental affection generally less, but among those cases affected psychosis occurred with greater frequency.

MORAL DISORDER.

In classification of the symptoms, definite distinction has been drawn between disorder of conduct and moral disorder, since the former may exist in marked degree, without any element of the latter, and also a certain amount of conduct disorder may depend on physical involvement, an aspect to which further reference will be made. Of the whole series, 12 patients exhibited moral change, but none of these came from Group 2. Among the symptoms met with in such cases were observed the following: uncontrolled use of bad language, gross cruelty, pugnacity and violence, thieving, lying, mythomania, in which the patient seemed unable to refrain from telling the most obvious untruths or from ridiculous exaggeration, truancy from school, running away, begging, marked and precocious erotism, masturbation, indecent exposure, incest, sodomy, or indecent assault. No somatic sexual precocity, such as that noted by Wimmer,[1] was observed, however. Among young males there was naturally a greater tendency to the more violent type of disorder, such as criminal or indecent assault.

DISORDER OF CONDUCT.

Change in conduct, too, proved much more common among children and adolescents than among adults, two-thirds of the 33 cases exhibiting such changes falling into Group 1. Every degree in change of conduct was noted, from the acquisition of some particular habit to conditions in which almost an entire change of personality was involved. Grimaces, noises, nail-biting, carelessness as to, or perversion of, daily habits, singing, jumping, mercyism, and spitting occurred.

Patients suffering from disorder of morals and conduct often showed themselves quite amenable temporarily, as if enabled for the moment to exercise voluntary control—when, for a short time, indeed, many of them would exhibit acute consciousness of their shortcomings; but as soon as outside influence was withdrawn their symptoms would return. Voluntary attention was frequently diminished, but instinctive attention was markedly increased, the patient showing an abnormal degree of curiosity. Though the intelligence quotient, as measured by Stoddart's modification of the Binet-Simon tests, was found to be very much below normal in several cases, it was difficult to determine whether any actual impairment of intelligence was present, since the poor response to a test might be accounted for by the derangement of attention just described, or by bradykinesia and bradyphrenia of the patient—the first preventing adequate continuity of concentration, the second group of factors causing rapid fatigue and disinclination for mental effort generally. Any defect of intelligence so recorded, therefore, would appear to be rather of a functional character, than to be due to any organic brain involvement.

PSYCHOTIC SYMPTOMS.

A resemblance was noted between patients suffering from epidemic encephalitis and those afflicted with such psychoses as manic-depressive insanity and dementia

praecox. There were found to be distinct points of difference, however, between the mental disorders of epidemic encephalitis and the psychoses which they resemble. The delusional state of epidemic encephalitis is more transient and variable than that of chronic delusional insanity. The mental outlook is objective and the immobility bradykinetic in those cases which resemble melancholia, but which differ from it for those reasons. The apparent katatonia of epidemic encephalitis is rather bradykinetic and bradyphrenic than part of the introversion of dementia praecox.

PSYCHONEUROTIC SYMPTOMS.

Cases closely resembling definite types of psychoneurosis were not of common occurrence, and apparently bore no relation to the age of the patient. Well-marked psychasthenic symptoms, however, occurred in a few cases. At first sight the similarity between the mental symptoms of epidemic encephalitis and those of the psychoneuroses appears a strong one. On thorough investigation, however, it is found that there are two important differences. In the first place, the former may clear up and disappear quickly without the application of any treatment, while the latter, in the absence of psychological treatment, tend to pursue a chronic course or to improve very gradually. Secondly, the effects of psychotherapy on post-encephalitis tend, with certain exceptions, to be of a transient character, while in the psychoneuroses permanent recovery may be looked for. In other words, by psychological treatment in epidemic encephalitis we are only dealing with what has been vaguely described as the "large functional element," which is present in many organic nervous diseases, whereas in hysteria and the psychoneuroses we are concerned with conditions which, if not of psychogenic origin, are at any rate much more dependent upon psychic factors.

Among those who support the psychogenic theory of the causation of this condition considerable claims have been made for the value of psychological treatment. Apart from extravagant claims, however, psychotherapy has proved of definite value as a symptomatic form of treatment in a number of cases—this especially in the cases where insomnia or sleep inversion occurred. The method of treatment was mainly that of suggestion, and the effect was quickly obtained. The various "stunt" methods of suggestion which have been described, such as the injection of innocuous substances, do not appear to be of value since they have no sound rationale and can only be transient in effect. In intelligent patients, where a large so-called functional element is superimposed on the organic trouble, psychotherapy may be of considerable and lasting benefit.

Memoranda:

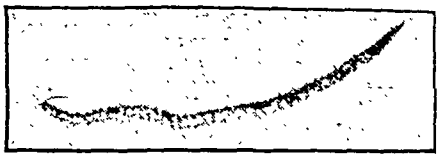
MEDICAL, SURGICAL, OBSTETRICAL.

A CENTIPEDE IN THE NOSE.

A STONEMASON'S labourer, aged 28, recently presented himself to me with the following history.

For two or three years he had suffered from difficulty in nasal breathing, deafness, slight vertigo, and headache. For the past few weeks, however, one nostril seemed to be definitely obstructed, and tightness and irritation in his nose caused insomnia and sneezing. Involuntary nasal whistling occurred from which he sought relief by breathing through the mouth. One morning, when he was trying to clear his nose, a large and very active centipede was ejected through one of the nares. With some difficulty he captured the centipede alive and brought it to me in a box. Since that morning his nose has felt altogether more comfortable; the difficulty in nasal breathing and the local irritation have practically ceased. Examination of the nares showed enlarged turbinals and a deflected septum, but there was no ozoena and no sign of gross trauma. The patient does no gardening and has no recollection of smelling flowers at any time in the past two months. On the other hand, his story that the insect came from the nose and nowhere else was very clear.

Cases of nasal infection by insects, though rare, do occur in this country. Greenbottle and bluebottle flies (blow-flies), even in Great Britain, occasionally deposit their ova in the human nose or ear, extensive ulceration and actual necrosis of the soft parts and even of bone being produced as these ova mature. Such ova have even been found in the anterior chamber of the eye, having reached there probably by way of the nasal sinuses. How easily blow-fly infection may occur must be known to many who were on active service in the tropics and saw cases of wounded being taken up with masses of flies adhering to their eyes, mouth, and nose. Blow-flies will lay their eggs on any open sore, and in Gallipoli and other war zones the sufferings of the wounded were often aggravated by this cause. Wounds or



ulcers infected by larvae must be dealt with promptly and thoroughly. They should be irrigated with a 1 in 20 carbolic solution or swabbed with pure benzine. Tumours resulting from the pressure of larvae should be freely opened and the contents expressed. Iodine seems to be inadequate; I have poured iodine upon a mass of writhing maggots without producing any apparent effect upon their vitality. Gad-flies, or bot-flies, whose maggots live in certain tumours in the skin of oxen, in the stomach and intestines of horses, and in the nostrils and other cavities of sheep, goats, and deer, have occasionally produced nasal infection in man, leading to inflammation and even necrosis of tissue. The grey flesh-fly, common everywhere in summer and autumn, in place of eggs produces living maggots which have sometimes been observed in abscesses in the human nose and ear; they number 50 to 80 in a swarm and change to pupae in five to eight days, developing into flies eighteen to twenty days later.

On the whole it appears probable that the centipede did not enter the patient's nostril in its adult state, but was accidentally transferred there at some earlier phase of its development. The photograph, which could be taken only after the creature had been chloroformed, gives but a poor idea of its normal active appearance.

Eastbourne. J. GORDON WILSON, M.D., Ch.B.

ILEO-ILEAL INTUSSUSCEPTION DUE TO A FIBROMA.

THE occurrence of a case of intussusception in an adult is sufficiently unusual to merit recording.

A miner, aged 25, was admitted to the Nottingham General Hospital with a history of having had, during the past four months, five attacks of vomiting associated with pain referred to the umbilicus. This pain was described as one of distension; it was accompanied by rumbling as though wind was trying to pass. Defaecation gave relief, but latterly aperients in increasing doses had been required.

The abdomen was distended with a well-marked "ladder pattern"; it was tympanitic and there was some epigastric tenderness. Rectal examination revealed nothing abnormal. An enema produced a constipated result, subsequent to which the bowels were well opened naturally.

Through the right linea semilunaris the peritoneal cavity was opened; small gut distended to the size of the patient's fist presented with collapsed coils of ileum below it. On passing the hand down into the right side of the pelvis a mass could be felt like an intussusception; this was brought up into the wound and proved to be one of the ileo-ileal type. Reduction was easy, only about two inches of gut being involved. At the apex of the intussusception a lump could be felt in the lumen of the bowel, so after applying a clamp across the loop the intestine was opened longitudinally and a tumour about 2 inches by 1 emerged; this was cut away along with its short pedicle. The wound of the intestine was then stitched up transversely with a loop on the mucosa stitch and a superimposed Lembert suture. Before releasing the clamp the ileum proximal to it, which was not only greatly distended but also hypertrophied, was lightly clamped for a small area, and a purse-string suture was inserted. At the middle of the area a puncture was made, and a large catheter was inserted. On removing this second clamp much flatus and several ounces of faecal fluid escaped through the catheter. As the catheter was withdrawn the purse-string suture was tied and the puncture wound then buried. The abdominal wound was repaired, a muscle drain being inserted.

The patient made an uninterrupted recovery, and six months later wrote "I do not feel anything from my operation."

Dr. Kilian Clarke, pathologist to the hospital, reported that a section of the tumour showed it to be a pure fibroma.

I wish to acknowledge my indebtedness to Mr. C. H. Allen for permission to treat and describe this case.

Nottingham. J. LLEWELLYN DAVIES, M.B., F.R.C.S.

AN UNUSUAL INJURY TO THE PATELLA.

THE following case may be of interest, having regard to its comparative rarity.

I was recently called to a woman who, while chasing her husband round a table, struck her right knee against the table-leg, and found that she could not move the limb immediately afterwards. On examination the leg was found to be partly flexed at the knee-joint, and was "locked." Where the patella is normally found was a marked angular swelling, which on palpation proved to be the patella. The blow on the medial edge had dislocated the bone by rotation on its ligament, and it had come to rest between the lateral and medial tibial surfaces of the femur. Manipulation was attended by severe pain, but, under an anaesthetic, reduction was easily made by flexion of the knee and "rotation" of the patella into position. After twenty-four hours free and painless movement, without effusion, was obtained.

Newhall, Burton-on-Trent. E. M. R. FRAZER.

Reports of Societies.

ULTRA-MICROSCOPIC VIRUSES.

DISCUSSION AT THE ROYAL SOCIETY.

SIR ERNEST RUTHERFORD, O.M., P.R.S., presided over a discussion at the Royal Society, on February 28th, on ultra-microscopic viruses infecting animals and plants. So much interest was evinced that a continuation was arranged for March 14th. On this occasion, unlike ordinary meetings of the society, the proceedings took the form of a conference, without set papers.

The Work on the Filterable Virus and some Unsolved Problems.

SIR CHARLES MARTIN, F.R.S., who opened the discussion, said that the discovery of the first filterable virus was made by a Russian botanist nearly forty years ago; he was looking for the cause of mosaic disease in tobacco, and, failing to detect any visible microbic agency, filtered the juice of the infected plant through a porcelain filter and found the filtrate infective for healthy plants. Later, Loeffler and Frosch discovered that the contagia of foot-and-mouth disease could be passed through a porcelain filter. Many pathologists then started investigations from this point of view on diseases which seemed to have no adequate cause, with the result that now more than a hundred diseases were attributed to invisible or filter-passing organisms. These viruses included bacteriophage, supposed to be an ultra-microscopic organism parasitic in bacteria, and those of various plant, insect, and mammal diseases. In this group of diseases had been included the various poxes, also nervous diseases such as poliomyelitis and encephalitis, sand-fly fever, dengue, yellow fever, possibly measles and mumps, and even influenza. Typhus fever and Rocky Mountain spotted fever had also been placed, perhaps unjustifiably, in this group. The members of the group had nothing in common clinically or epidemiologically. In some cases the path of infection was direct; in others it was through air, or by food, or the bites of insects. The only passport for inclusion in the group was that somebody had succeeded in getting an infective filtrate through a filter designed to keep back ordinary micro-organisms. The group was continually having new admissions and expulsions. Chicken diphtheria, for example, had been expelled, also trachoma and scarlet fever, on the ground that a microbial origin had been satisfactorily established for these diseases. One feature about certain of these virus diseases, not common to bacterial diseases, was the cellular response of the host by the formation of curious bodies in some of the cells affected. Whatever their true significance might be, they were so characteristic that in some cases they could be used for the diagnosis of the disease.

Varieties of Filters Used.

Turning to filters and their structure, Sir Charles Martin said that these were of two kinds: mineral filters made of unglazed porcelain of different grades or of diatomaceous earth with a little asbestos, or colloidal membranes of different permeabilities. A good deal of work had been done in the endeavour to determine the average size of the pores; one method rested on Poiseuille's law, another on the amount of pressure involved in overcoming the surface tension by blowing bubbles, but the latter involved a good many assumptions which did not seem justified. Whether the particle would pass through the filter or not depended not only upon the dimension, but upon the action between the particle and the walls of the crevices, and upon whether the particle was rigid or could be distorted radially or was capable of motility of its own. Finely ground porcelain would stop particles of about the order of 0.2 micron, and coarser ground of about the order of 0.5. Anything above 0.2 micron being held back, it was obvious, in view of the limit of resolution of the microscope, why anything that went through should be invisible. It was merely a coincidence that these organisms should be invisible as well as filterable. The range of discovery, however, could be increased by the use of ultra-violet light, and he understood that Mr. Barnard, with a wave-length of about 250$\mu\mu$, had been able to photograph particles down to a size of 0.08 micron. Some of the viruses ran through the filter without any serious fall in concentration; others appeared only to pass through the filter by accident. Among the good filterers were the viruses of mosaic diseases, foot-and-mouth disease, and the Rous sarcoma; on the other hand, the viruses of typhus, trench fever, and Rocky Mountain spotted fever might have been passed through some of the coarser filters, but most of the people who had tried the experiment had not been successful, and the same was true of the poxes, with the exception of the particular strain of vaccinia virus discovered by Levaditi and called neuro-vaccinia. The virus of canine distemper was a filter-passer, but a poor one, and for many years it awaited verification.

The Process of Filter Passing.

What were the dimensions, then, of some of the good filterers? There were many pitfalls in trying to determine this point. Experiments had been made in filtering through collodion membranes of different permeabilities, and testing the passage of particles of known size. Colloidal solutions of arsenious sulphide had been used, also collargol, a colloidal suspension of silver, both of which had particles of a definite order of size. Although the experiments of some investigators suggested a much smaller size—the virus of foot-and-mouth disease had been stated from one series of experiments to be not bigger than one of the smaller protein molecules—yet a good many others had not been able to repeat these observations, and had given the order of magnitude of some of the good filterers as equal to that of collargol particles—that is, 20$\mu\mu$. How small could a living organism be? There must be a certain size for life to begin, because it involved an aggregate of molecules, and rather complicated molecules at that. It looked as if an alternative hypothesis was required as to the nature of these viruses. Some sort of catalyst had been suggested, but this the speaker found extremely difficult to visualize, and he preferred to consider that the dimensions were not of the small order suggested by some observers, and that these viruses were living organisms.

What was the simplest common measure of a living organism? First, the capacity to take dissimilar molecules and make them into molecules similar to its own; secondly, multiplication; thirdly, variation, following upon not quite perfect assimilation. After careful consideration of all the facts of which he was aware, he had not been able to find any essential distinction between viruses and microbes except their size and cultivability on inanimate materials. The viruses being so very small, perhaps their powers of assimilation were extremely limited, and therefore required to have their foodstuffs prepared three parts of the way before they could use them to build up new viruses. The evidence that they had been cultivated apart from living cells was unconvincing; many of them had been cultivated in symbiosis with living cells and in glass vessels. Bacteriophage could be cultivated in growing bacteria, Rous sarcoma in pieces of spleen tissue, and Rocky Mountain spotted fever and typhus had apparently been so cultivated, or at least the virus had remained alive for a very long time. It looked as though they were obligatory parasites, and support was given to that view by the apparent

absence of the saprophytic virus. With ordinary micro-organisms only a fraction of 1 per cent. were pathogenic to animals or plants; the others subsisted upon inanimate material.

Finally Sir Charles Martin emphasized some of the difficulties in the work on filter-passers. Work with an agent which could not be seen or propagated in the ordinary way, and in which every single observation required the inoculation of an animal or plant, and a period of waiting of perhaps weeks or months for the answer "Yes" or "No," was rather heartbreaking. No method was available for securing pure cultivation of viruses. Freedom from external contamination might be secured, but if two viruses got mixed up there was no simple method of separating them except by inoculating them into animals which would be immune to the one and not to the other. It was extremely difficult to decide in a human disease whether it was due to a filter-passer or not. It seemed absurd, for example, that after all these years it should still be uncertain whether influenza was due to a filter-passer or to such an organism as Pfeiffer's bacillus. If there was *any animal* which could reproduce the disease, many people in that room could give the answer to the question within a fortnight.

Virus Diseases of Plants.

Professor P. A. MURPHY said that virus diseases of plants gave the impression of being a more homogeneous group than animal virus diseases appeared to an outsider. The difficulty was that while it was easy to filter the sap of a plant and to obtain a filtrate free from any visible life, in numerous diseases of plants presumed to be virus diseases it was not possible by mechanical means to infect the plant with the filtrate. On the other hand, virus diseases could be transmitted from plant to plant by grafting or pruning, and this was looked upon as the hall mark of virus disease in plants. Furthermore, many of them could be transmitted by an appropriate insect vector. It was characteristic of virus diseases of plants that they were systemic and affected all the plant tissues —leaves, stem, root, everything except the seed—which, among plant diseases in general, was very unusual, and suggested that the agent producing these virus diseases was entirely distinct from the fungi, bacteria, and occasionally protozoa which produced other diseases in plants. Unlike animals infected with virus diseases, the majority of the plants infected were carriers.

Dr. KENNETH SMITH dealt with the insect carriers of plant viruses. Was the insect the host of the virus or merely a mechanical carrier? In the mosaic group of diseases it was fairly obvious that the insect was not any more than a mechanical carrier, but in certain other plant diseases the virus was spread only by one particular insect, and in such case it would appear that there was some obligatory action between the virus and the insect. As to the length of time for which the virus remained infective in the body of an insect carrier after it had no longer access to the infected plant, in one case the insect had been found infective after two months' feeding upon a plant which was immune. The offspring of infected aphids had been found not infective to the healthy plant.

Dr. J. A. ARKWRIGHT, F.R.S., added a short contribution on the virus in foot-and-mouth disease in animals, which virus, he said, was easily filterable. The infectivity of foot-and-mouth disease among naturally susceptible animals was very high. After an attack of the disease the animal was completely resistant for a time, not for as long as the immunity after scarlet fever or measles, but for longer than that after herpes or erysipelas. During the period of immunity the blood contained antibodies, which could be shown experimentally to neutralize the virus.

Ultra-microscopy with Ultra-violet Radiation.

Mr. J. E. BARNARD, F.R.S., explained some of the difficulties from the microscopical side. With a view to trying to improve the microscopical method, he had almost entirely devoted himself to the light of shorter wave-lengths. It must be remembered that, in addition to their minuteness, these viruses might possibly have other characteristics; their optical quality in terms of visual light was not different from that of the medium or body fluid in which they were, and this prevented them from being seen by any means ordinarily available. While, however, this characteristic might hold good for a given range of wave-lengths, he could not imagine that it was true for all available wave-lengths. If a body had the same refractive index as its medium for, say, the middle part of the visible spectrum, it was highly improbable that it would have the same optical constants in some part of the ultra-violet. Again, the light used in microscopical work determined in large part the order of resolution; therefore, it appeared that with light of shorter wave-lengths it should be possible to see some of the characteristics of a body which was smaller than could be seen by visual light. On the physical side the perfection of a microscopical apparatus for use with radiations extending down to the limit of transmission by quartz presented in theory no difficulty at all. The practical difficulties, however, were very considerable. He had now collected a fair amount of apparatus whereby one could, with reasonable certainty and fair accuracy, photograph bodies and organisms of smaller size than was possible with the ordinary microscope. One of the difficulties with ultra-violet radiations was that any source of light used must be of the nature of a spark. To get anything like a photograph of value of a body which was in fluid, and therefore often in rapid motion—if not motion of its own, certainly in rapid Brownian motion—such a photograph had to be obtained in an extremely short time. One recent development was a dark-ground illuminator for ultra-violet rays, and by this means it was hoped to reduce the exposures to more workable limits. Mr. Barnard showed on the lantern screen a number of results obtained by this method, revealing clearly fine differentiations of granules of an order of size of something less than 0.2 micron.

Sir ERNEST RUTHERFORD asked Mr. Barnard what ratio his experiments with ultra-violet rays bore to the ordinary microscope in respect to the size of image obtained.

Mr. BARNARD replied that if an organism of the order of size of 0.3 micron could be properly seen by an ordinary microscope, using a wave-length of 5,000 Angström units, then, working with 2,500 Angström units, one should be able to see satisfactorily an organism of the order of 0.08 micron. Asked whether there was any likelihood of getting beyond this, Mr. Barnard replied that the only limitation was the difficulty of getting fused quartz of requisite quality.

Filterable Tumours.

Dr. W. E. GYE said that the filterable tumours of fowls, discovered by Peyton Rous, constituted an exceedingly important group of new growths because an effective filter-passing agent could be extracted from them easily. In this respect they contrasted sharply with the tumours of mammals. The agent might be obtained in various ways, but he and those working with him had found that the method of obtaining it in greatest concentration or activity was to treat the tumour tissue with a saturated salt solution which he described. The filtrate obtained was usually infective in doses of about 0.001 c.cm., and the tumour produced was a true tumour developed from the connective tissue of the animal which was inoculated; from this tumour further infective filtrates might be obtained. The the essential phenomena encountered in filterable viruses were met with here—namely, that apparently the agent could reproduce itself indefinitely in the infected tissues of the animal. There was a large group of filterable tumours of very diverse structure and biological character, all yielding an infective filtrate specific to fowls, and each infective filtrate gave rise only to tumours of the type from which it was obtained. If, for example, a fowl were inoculated in one breast from a filtrate of spindle-cell carcinoma and in the other from a filtrate of endothelioma, the original tumour in each case would be imitated. When Rous first discovered these filterable tumours most investigators refused to accept them as true tumours, but today, after eighteen years, they were universally admitted to be actual new growths. The filterable agent had given rise to a good deal of controversy. In the belief of some physiologists it was an enzyme. One French investigator rejected both the virus and the enzyme, and declared that the agent was a "physico-chemical principle," whatever that might mean. Dr. Gye went on to refer to

destruction or loss of activity of the filtrate on incubation, a characteristic which he had been studying now for some years. In respect to this property also it resembled a good many filterable virus diseases. He concluded with some remarks on antiseptics. The agent of these tumours, whatever its precise character might be, was susceptible to the whole range of antiseptics as known and applied to ordinary bacteria. The general conclusion was unavoidable that the action of antiseptics upon these agents was the same as that which was expected and known to occur in the case of ordinary organisms. One antiseptic which he had studied with special care in this connexion was acriflavine, which would act in the presence of serum. If one tried to kill the virus of bovine pleuro-pneumonia with acriflavine in the presence of serum, should the serum be inactivated by heat or by old serum, the dilution of acriflavine required to kill the organism was 1 in 5,000, but if the serum was fresh, then the virus of pleuro-pneumonia could be killed at dilutions of 1 in 40,000 or 1 in 50,000. Exactly the same thing applied to the action of acriflavine on the filtrates of the tumours of which he had been speaking, and from such evidence as this he was convinced that the agents in these tumours were of the same order as the pleuro-pneumonia virus, and also that these organisms were of the same order as ordinary bacteria.

At the adjourned discussion, on March 14th, Professor Ledingham and others are to speak.

RADIUM TREATMENT OF MALIGNANT DISEASE OF THE UTERUS AND OVARIES.

A MEETING of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine was held on February 15th, with Dr. J. S. FAIRBAIRN in the chair, when Professor J. HEYMAN (Stockholm) read a paper on the uses of radium in the treatment of malignant disease of the uterus and ovaries.

Professor Heyman opened by stating that for a long time it had been known that certain carcinomas could be cured by radiological treatment, the term "cure" meaning the absence of recurrences for a period of five years or longer; cancer of the uterus belonged to this category. Radiological treatment, when carefully adjusted, excited a healing process characterized by destruction of the tumour cells and regeneration of the tissue which was the seat of the destructive process. So in a cured cervical cancer the cervix and vagina were found to be restored to their normal outlines. In most cases, however, a moderate atrophy of the uterus and vagina remained. Only those who had been engaged in radiotherapeutic work for some considerable time were fully able to realize the exceedingly great care and precision with which radiotherapy had to be handled, and the severe damage which might be inflicted on a number of patients by unskilled operators. The Radiumhemmet, founded by Forssell in 1910, was a special clinic for radiotherapy, particularly intended for the treatment of malignant growths; and, from the very beginning, treatment was only applied in the case of inoperable malignant tumours. When undoubted results had been gained in these cases, the treatment of borderline cases, and, lastly, operable cases, was undertaken. Thus, during 1910–18, the inoperable cases in the series made up 80 to 90 per cent. of the total number. But, none the less, in these inoperable cases, five-year results fully comparable with the best results obtained by surgical operation were realized. Forssner and Essen-Möller had led the way in submitting operable cases of cancer of the cervix for radiological treatment. During the period 1914–23 inclusive, 737 cases of carcinoma of the cervix had been treated at the gynaecological department of Radiumhemmet. The follow-up department was efficient, and was greatly aided by official Government recognition. Of the 737 patients primarily radiologically treated, 170 were alive, free from recurrences five years after the treatment—23.1 per cent. five-year cures. During the period 1914–23, 188 operable cases were treated; of these, 82 were alive, free from recurrences after five years—43.7 per cent. cures among operable cases. Inoperable and borderline cases during the same period numbered 549; of these, 88 patients were cured and alive, free from recurrences after five years—16 per cent. of cures. A detailed account of the treatment would be found in *Acta Radiologica*, vol. x, fasc. 1. Professor Heyman maintained that the governing principle in the local radium treatment was the small number of relatively heavy doses given within a relatively short period of time, and at intervals adjusted with reference to reaction and course of healing. Thus, within a month, there were three applications which occupied from nineteen to twenty-three hours, and in every case a filter equivalent to at least 3 mm. of lead was used. Finally, percutaneous treatment with radium at a distance showed remarkable primary results; for this at least 2 grams of radium were required. Forty-six patients with cancer of the body of the uterus had been treated with radium from 1913 to 1921; 45.7 per cent. were inoperable. Of these, 20 were alive and free from symptoms at the end of five years—43.5 per cent. In the treatment of cancer of the body the same principles were followed as in cancer of the cervix, the vaginal dose being decreased. Operation was advised if at the end of about two months after treatment symptoms of recurrences appeared. Radiological treatment alone would not yield any lasting results in carcinoma of the ovaries, and it was necessary to adopt a combined surgical and radiological treatment. Radium treatment in these cases was combined with x-ray treatment, and should the tumour become small and movable surgical aid was called in. It was of the utmost importance that the treatment of gynaecological cases should be left in the hands of the gynaecologist trained in radiology. The point was emphasized that the good results that had been obtained, although largely dependent upon the technique employed, were, perhaps, above all due to the fact that the treatment had been attached to a radiotherapeutic clinic.

ASTHMA.

AT a meeting of the Section of Medicine of the Royal Society of Medicine, held on February 26th, with Dr. R. HUTCHISON in the chair, Professor KARL HANSEN of Heidelberg read a paper on the allergic and psychical factors in asthma.

Professor Hansen said that asthma was a clinical term embracing a whole distinct symptomatology. He excluded all forms of cardiac, uraemic, and hysterical asthma, and dealt only with bronchial asthma, characterized by spasms of the bronchial muscles and increased exudation. At the present day the cause of this excitement of the parasympathetic nervous system was thought to be some allergen, and Professor Hansen stated that he intended to exclude non-allergic bronchial asthma. Dealing first with the phenomenon of allergy, he showed how Blackley had brought out an ingenious theory to account for hay fever many years ago, and how this theory was confirmed by the discovery of anaphylaxis fifty years later by von Behring and Richet, and applied clinically by von Pirquet, who introduced the conception of allergy. Professor Hansen then sketched briefly the theoretical foundations of allergy, and laid down the criteria upon which the diagnosis of an allergic disease could be based. These included an exact history, a positive result of the cutaneous test, the passive transferability of the cutaneous reaction to healthy persons through the serum of the diseased person, the inspection of the patient's environment, and the proof of the existence there of specific allergens, the experimental production of the disease by exposing the patient to the influence of allergens, and, lastly, the disappearance of the symptoms of the malady after the removal of the allergens from the surroundings of the patient. While a study of the exogenous factor was of importance in allergic diseases the endogenous factor must also be considered, for the presence of allergens in the surroundings of human beings did not necessarily bring about illness or an attack. In the first place, only a small percentage of mankind seemed to have any disposition to allergic disorders, and there was evidence that the allergic patient had inherited a particular constitution. Secondly, it was well known that animals which had been subjected to anaphylactic shock were for a time immune to the action of allergens, a principle utilized by Freeman in the treatment of hay fever by means of desensitization. This might explain the fact that patients susceptible to certain allergens could at times withstand the presence of

these allergens without any reaction at all. A third factor, frequently overlooked, was the conditions under which absorption of the allergens took place, as illustrated by the case of a workman who for years had applied a certain preparation to furs by means of a paint-brush, but only had his first attack of asthma when he used this preparation, to which he was sensitive, in a spray. Climatic influences also played a part in altering sensitiveness, and so also did various influences of periodicity in the course of life, as, for example, was shown by the greater tendency of asthmatic women to suffer attacks shortly before menstruation. Professor Hansen next discussed the significance of the psyche in the production and control of organic disturbances. He expressed the view that the "person" alone was in the proper sense the subject of biological and clinical observation and treatment, a view which must involve a study of the relations of the psyche to the body. An investigation into the psychical factors in disease was very difficult, and liable to serious errors. Nevertheless, it was important to discover if psychical factors could be proved to influence the disposition to disease in the face of known pathogenic substances affecting the organs. The study of asthmatic patients under the influence of hypnotism gave some help, but there were many indeterminable influences at work. Professor Hansen then described in detail the life-history of an asthmatic patient, aged 50, who had suffered from the malady since 10 years of age. This patient showed a positive cutaneous reaction to horse dandruff and to bed feathers, and had frequently experienced attacks if she inhaled the dust when bedding containing feathers was shaken near her. She also revealed a complex psychological situation, and there was a remarkable association between the asthmatic attacks and certain emotional experiences. Professor Hansen finally sketched his theory of the association between allergic and psychical factors in asthma. It seemed that in asthma there was an ever-renewed intrusion of allergens into the organism, but, except in extreme cases, these intruding physical agents only led to a derangement expressing itself as illness when they found the body prepared by certain psychical experiences. It was certain, said the speaker, that the vegetative nervous system played a most important part.

Dr. M. CULPIN, in opening the discussion on Professor Hansen's paper, said that the subject of asthma was full of difficulties for the clinical psychologist. In the literature it was possible to find the case described by Professor Hansen very closely paralleled. He described a case under his own care in which asthma had been present for twenty years, brought on by very different stimuli, which, on investigation, were shown to be linked together by association of ideas. Following the revelation to the patient of this association the attacks ceased. In patients subject to pathological states of anxiety there occurred attacks of "panic" in which, together with the psychological disturbance, various objective signs of fear were present, and in some cases symptoms of cardiac or gastro-intestinal disorders appeared, replacing the anxiety state. Asthma might bear a similar relation to the anxiety state, but Dr. Culpin emphasized that this claim was neither absolute nor exclusive. He looked upon the allergic phenomena as "freakish manifestations of a biochemical Puck," and he thought some help in correlating them with the psychic factors might be found in the study of conditioned reflexes.

Dr. R. D. GILLESPIE said that the psychiatrist had not much opportunity for studying asthmatic patients, since they did not come to special hospitals dealing with functional nervous disorders. In the literature there was also a paucity of references to the psychological aspects of asthma. It would be instructive to know how many neurotic subjects had had attacks of asthma in their previous history. He was interested in the discussion of the possible symbolic value of asthmatic attacks, but he thought it important to distinguish psychogenic dyspnœa from true asthma. He thought that asthmatic patients might be looked upon as having a constitutional pattern which could express itself as an asthmatic attack.

Dr. E. P. POULTON referred to some experiences with migraine, an allied disease in his opinion, which illustrated the effect of psychical factors in influencing the disorder.

Dr. G. H. ORIEL recounted a case in which, following a severe emotional experience in the home, a girl developed angioneurotic oedema, and her mother urticaria. Later, when affairs were settled, it was found that the daughter, who had developed egg sensitiveness, had once more become normal. He referred also to the high blood sugar of the anxiety state, which appeared to develop through the action of the endocrine system.

Dr. A. P. CAWADIAS said that he had seen cases of asthma develop after emotional upsets, but such patients also reacted to certain allergens. Treatment by diet and specific anti-anaphylactic remedies removed the asthma. He thought that the explanation of the interrelation of the psychic and allergic factors would come with a better knowledge of the vegetative nervous system, recent work on which was vague and meagre.

Dr. E. PARKES WEBER thought it was impossible to get away from the fact that psychic factors could influence asthma. The reaction of the body to the psychical factors of disease depended largely on the pattern of the individual. The effect produced was analogous to that of physical agents in the familiar "seed" and "soil" hypothesis.

Dr. G. GRAHAM inquired what part adrenaline played in the relationship between psychical factors and asthma. In his view it was very important to obtain a method for estimating the amount of adrenaline in the blood.

DEATHS UNDER ANAESTHETICS.

AT a meeting of the Section of Anaesthetics of the Royal Society of Medicine on March 1st, with Dr. ASHLEY S. DAY presiding, a paper was read by Dr. GERALD M. SLOT on deaths under anaesthetics, with special reference to their pathology.

Dr. Slot said that the material upon which the paper was based had been obtained during the last five years, through the courtesy of certain of the London coroners, in respect to anaesthetic deaths occurring within their jurisdictions. Broadly speaking, the *post-mortem* findings in deaths from anaesthetics could be classed under five headings: (1) status lymphaticus (a very small but definite proportion of cases); (2) some gross accident during the administration of the anaesthetic; (3) such abnormalities as were frequently present in cases other than anaesthetic cases (for example, myocarditis, arterio-sclerosis), and in which the anaesthetic could not be regarded as culpable; (4) gross disease, such as intestinal obstruction or general peritonitis, in which the prior condition of the patient must have been precarious; (5) changes occurring in deaths under spinal anaesthesia and also nitrous oxide anaesthesia. It was not possible for the pathologist to state, except in cases of grossest overdosage, how much anaesthetic had been given. The smell of the anaesthetic noticed on opening the thorax varied according to the time at which the examination was made after death. The *post-mortem* findings in status lymphaticus were quite definite, including enlargement of the thymus, hyperplasia of the glandular tissue at the base of the tongue, usually some excess of the tonsils and oral lymph tissue, and hyperplasia of the lymphatic tissues of the gastro-intestinal system, the stomach having a characteristic "sago-like feel." There was usually, but not always, enlargement of the abdominal lymphatic glands. Dr. Slot discussed the morbid physiology and pathology of the thymus in relation to these deaths. One of the first things the pathologist considered was the weight of the thymus gland, but it was very difficult to be dogmatic about this, more especially as the scales for ascertaining weights in mortuaries were usually defective. He believed that in status lymphaticus there was a general dyscrasia of more than one endocrine organ, and the thymus was not alone inculpated. He noticed a similarity between deaths occurring in this condition and deaths from anaphylaxis. So many different opinions were held as to the cause of death in status lymphaticus that it was evident the real cause was not yet known. With regard to deaths occurring as a result of gross accident in administration, as a rule the *post-mortem* changes were quite obvious, including the red and oedematous condition of the buccal and oral mucosæ and congestion of the lungs, which smelt strongly of the anaesthetic. Death in these cases was probably due as much to shock as to any other factor. He described three recent cases which he had investigated, and in each case

in his opinion, the anaesthetist was entirely blameless. In the first case there was pulmonary embolism, which he believed to be more frequent than was supposed in anaesthetic deaths; in another there was acute pulmonary oedema, and death was probably due to the asphyxial effects of the oedematous fluid; and in the third there was coronary thrombosis. In discussing various theories of the action of anaesthesia Dr. Slot mentioned that he had tried to verify the assertion that the anaesthetic increased the fluidity of the lipoid cells, but without success. Speaking of various anaesthetics, he said that in the cases he had investigated only two deaths had been definitely due to ethyl chloride. This anaesthetic had a marked effect on the blood pressure. Vagus inhibition of the heart was more likely to occur with ethyl chloride than with ether. Respiration always ceased before circulation, an important point to bear in mind in restorative technique. With regard to nitrous oxide, his impression was that with short nitrous oxide anaesthesia death did not occur, though he had seen three deaths when nitrous oxide was used for a longer gas-oxygen anaesthesia, but in these cases the operations were of great severity, and his view, which was endorsed by the coroner, was that the patients had died from surgical shock. In nitrous oxide death, again, respiration ceased before circulation. With regard to chloroform, he was convinced that some of the deaths from chloroform were acidosis deaths. Delayed chloroform poisoning was not very common, but he had seen two fatal cases. In deaths under spinal anaesthesia which he had seen the *post-mortem* examination revealed nothing at all. It was said—but he had not seen it—that in these deaths there was evidence of asphyxia.

Mr. A. DOUGLAS COWBURN, one of the London coroners, substantiated as far as his experience went the main contentions of Dr. Slot. The distinction between deaths from an anaesthetic and deaths while under an anaesthetic was one which many people failed to realize. Death might occur from the effects of shock, due to surgical manipulation or otherwise; from toxaemia; or from the desperate measures to which the surgeon and anaesthetist had to resort in the case of a patient extremely ill; but very rarely had death occurred, in his experience, from what might be called an overdose of anaesthetic. The only exception was with ethyl chloride, which he frankly confessed he detested. He had himself seen it given, and had seen one death under it. When death did occur under ethyl chloride, however, it was usual to find that the anaesthetic had been given by some resident officer, not by an experienced anaesthetist. As to status lymphaticus, he agreed with Dr. Slot that it was ridiculous to give a diagnosis of this condition merely because the Malpighian corpuscles of the spleen were enlarged or because there was an excess of lymphoid tissue here and there. The thing must be looked at all round, otherwise the diagnosis only brought discredit. Three years ago an eminent surgeon told him definitely that he did not believe in the existence of status lymphaticus, which had been invented only to shield the anaesthetist. Mr. Cowburn was able to tell him from his personal experience of two deaths from status lymphaticus which had come under his observation in which no anaesthetic had been administered at all. The *post-mortem* appearances suggested status lymphaticus and nothing else. He gathered that Dr. Slot considered chloroform a dangerous drug. Many years ago, when the speaker was a hospital resident, the staff were told that young children, and also women in labour, could be given chloroform with impunity. Now he learned that pure chloroform was never given. Mr. Cowburn added a word as to the difficulties which medical men encountered in their work in public mortuaries. In the majority of cases the mortuaries attached to London coroners' courts were disgraceful; there was one conspicuous exception (Wandsworth): Paddington was better than the rest, and in his own jurisdiction (Southern and Clapham districts) he had been able to induce the authorities entirely to remodel one of the mortuaries, and to fit it with every convenience for the doctors to carry out their responsible duties.

Dr. JOSEPH BROMFIELD thought that both Dr. Slot and Mr. Cowburn had been too sweepingly kind to the anaesthetist. It had always seemed to him that the question of deciding the cause of death under an anaesthetic was extremely difficult. How was one to say that the cause was surgical shock and not the anaesthetic? With regard to the cause of death in spinal anaesthesia catastrophes, many believed that it was the extreme action of the spinal anaesthesia in lowering the blood pressure. He could not agree as to the dangers of ethyl chloride. It had never given him a moment's anxiety.

Dr. C. F. HADFIELD also said that he had had no anxiety with ethyl chloride, except on two occasions, both of them long ago, when he was less experienced. He agreed, however, that it was necessary to teach students how potent a drug it was, and how rapid in its action.

Dr. C. L. HEWER mentioned that in the dental department of the Queen's Hospital for Children about 2,500 cases were dealt with every year, and for the past fifteen years there had not been a single death. All the cases had ethyl chloride, and in about two-thirds of them the anaesthetic was given by residents who had no special experience.

Dr. Z. MENNELL thought the chief danger of ethyl chloride arose from the fact that the comparatively inexperienced did not realize what a powerful drug it was and how quickly anaesthesia occurred. He thought Mr. Cowburn was too hard on chloroform; in certain cases late chloroform anaesthesia was essential.

The PRESIDENT took the view that ethyl chloride was a dangerous drug, and he detected an inconsistency in Dr. Hadfield's remark that it was safe, but that students should be taught its potency.

Dr. SLOT devoted his reply chiefly to some further considerations on status lymphaticus, which, he said, was probably not one condition, but several conditions grouped together.

PROTEIN SHOCK THERAPY.

AT a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on February 15th, with the president, Dr. R. J. ROWLETTE, in the chair, Dr. V. M. SYNGE read a paper on protein shock therapy.

Dr. Synge said that treatment consisted in the intravenous injection of T.A.B. vaccine, two injections being given, the first containing 100 million *B. typhosus*, 50 million paratyphoid A, and 50 million paratyphoid B, while in the second injection, given five to seven days afterwards, there were double the number of organisms. In about an hour after injection a rigor occurred, with a sharp rise in temperature to 103° or 104° F. There was severe headache, with pain all over the body and sweating; in some cases there was vomiting with diarrhoea. Aspirin and, in some instances, morphine were given to relieve the pains. In cases which did well the temperature was always normal within twenty-four hours; if the temperature remained up for forty-eight or seventy-two hours there was never any improvement as a result of the treatment. Twelve cases (*chronic sciatica*, chronic arthritis, persistent muscular rheumatism) were treated. In most instances there was slight temporary benefit, in some no improvement whatever, and in a few cases permanent cure. Particulars of two illustrative cases were given as follows:

A man, aged 49, had had *right*-sided sciatica for nine years, with tenderness along the course of the nerve and wasting of the right thigh; the hip-joint was normal. He had been unable to work for nine months. After treatment the pain disappeared completely and the patient resumed work. When last heard of fourteen months after treatment he was still free from pain.

A man, aged 25, had had left-sided sciatica for four months. After the first injection there was a rigor with pyrexia, the temperature not becoming normal for forty-eight hours. After the second injection there was again a rigor, with high temperature, which did not fall for seventy-two hours. No improvement followed the treatment.

Dr. Synge said that this method of treatment was not new; it was often unsuccessful, but it deserved wider trial in chronic cases of sciatica and rheumatic conditions where ordinary methods of treatment had been employed and had failed. It should obviously not be employed in the case of feeble patients, or of those with cardiac disease.

The PRESIDENT said he had never understood why vaccines were the form of protein which were most commonly employed, since the T.A.B. vaccine, in addition to its

protein content, must contain a certain amount of toxin and cause some toxaemia, a complication which would be avoided by using proteins in which there was no toxin. The method of protein shock had been used largely in acute conditions, such as puerperal sepsis, but with poor results. It was, however, encouraging to hear of anything which gave immediate results in such an acute condition as sciatica. He wondered if the considerable burns which were produced by the use of Corrigan's button in this condition caused protein shock.

Dr. PRESTON BALL was disappointed that Dr. Synge had not obtained better results from protein shock therapy. He personally had treated fifteen cases, following the method advocated by Dr. Yeomans of Harrogate, with very good results. The objection which he personally found to the treatment was the extraordinarily alarming results which it produced. About an hour after the first injection the patient's temperature went up, sometimes exceedingly high; he looked and felt ill, but after a few hours the condition subsided. Dr. Ball had found the treatment successful in cases where there had been profuse sweating, occurring immediately after the injection, and the temperature had come down rapidly. He thought that in the case mentioned by Dr. Synge which had not been successful the result might have been good if the treatment had been continued. The routine course included at least five injections. In one case of his own in which, for unavoidable reasons, he had only been able to give two injections, the patient not only got no better, but became worse. He asked whether Dr. Synge considered it necessary to make sure that no kidney disease was present before giving the treatment, since T.A.B. vaccine contained a little carbolic acid, and was likely to produce haematuria. He regarded the treatment as being of very great value in cases where nothing else had succeeded, and where no focus of infection could be found.

Dr. E. T. FREEMAN referred to a paper which he had read before the Medical Section about four years ago on protein sensitization, and said he had first used this treatment for cases of chronic urticaria and similar conditions. He had at first used peptone, but now used T.A.B. vaccine; this produced a very rapid effect in a very short time. He mentioned a case of mucous colitis in which he had given about twenty injections; the motions had decreased from twenty a day to three a day. The patient had remained well for some months, but then returned to hospital, and was given an enema, which had started the colitis again; on this occasion the treatment had not been successful, and caecostomy had been performed. This case, he thought, showed that sometimes in the same patient, with the same condition, the results would vary. In cases of bony involvement he had found that the treatment sometimes brought about alleviation of pain, but the results were never permanent. He also referred to a post-puerperal septic case in which no septic focus had been found, and in which he had suggested an injection of mercurochrome. One hour after the injection the patient's temperature had gone up to 107° F., and had remained very high for four days; it had then dropped to 100° F., and had never risen above that, the patient making a complete recovery. Dr. Freeman thought that the great objection to this method as a routine was that it was utterly impossible to foretell the result, and nothing could be promised to the patient; some did very well, and others did not. It was an unpleasant treatment, and he thought that if it were possible to know the kind of case that would respond to it, it might be used with greater assurance and greater frequency.

Dr. G. E. NESBITT referred to the great variety of proteins and the different degrees of shock which they produced. The procedure seemed to be largely on the lines of the malarial treatment of parasyphilitic infections, a method which he personally disliked; he did not think it would succeed as a permanent form of therapy. He asked whether Dr. Synge had made any observations on the white cell content in his cases, and said this might be of interest in view of the different results which would be obtained. The leucocyte reaction might have varied, and it would have been interesting to know if it was positive in successful cases and negative in unsuccessful ones.

Dr. W. G. HARVEY referred to the difficulty of knowing exactly what protein shock was; he thought the term "non-specific therapy" might be more applicable than "protein shock therapy." He referred to a case of lupus erythematosus which had been particularly resistant to treatment. The patient, while in hospital, had had an attack of rheumatic fever lasting for about three weeks; at the end of this time the lupus erythematosus had cleared up completely and absolutely.

Dr. A. B. CLERY mentioned the case of a man who, before going to France in the war, had had two injections of T.A.B. vaccine. While in France he had contracted trench fever, and had afterwards suffered from very severe pain in the legs, recurring every month or two months, and made much worse after taking even a small amount of alcohol. When seen by Dr. Clery after the war he had had a small varicose vein in his leg, and Dr. Clery sclerosed the vein in order to relieve the pains. The vein disappeared, but the pain still continued. Dr. Clery then gave a third injection of T.A.B. vaccine, subcutaneously; the same evening the patient's temperature had risen to 102°, the next day it was 100°, and the third day normal. Since then the patient had remained perfectly well, and had had no recurrence of the pains.

Dr. SYNGE, replying, said that the reason he preferred T.A.B. vaccine to other forms of protein was because it was a standard preparation; it was therefore easy to decide on the amount which should be given at each injection. In asthma he believed that large doses of peptone had been given to produce shock, but he personally had never tried this, and thought that in this disease it might not be altogether safe. It was unlikely that the small amount of carbolic acid contained in the vaccine could produce haematuria, though the method might be unsafe in patients whose kidneys were bad. He had not investigated the white cell count in his cases. The treatment was unpleasant; many patients after one injection refused to have a second, and some who had had two refused to have a third. If improvement did not occur after the first, or at any rate after the second injection, he thought it meant that the treatment was not going to be successful. If it was an unpleasant treatment it was harmless, and the cures amounted to 20 or 25 per cent., which, in his opinion, rendered it a treatment which was worthy of trial.

Congenital Pyloric Stenosis.

Dr. R. E. STEEN read a paper on congenital pyloric stenosis dealing chiefly with diagnosis and treatment. He emphasized the importance of obtaining a careful history, and concluded that if the diagnosis was not suggested here it would probably be missed at the routine examination. He regarded the association of vomiting and constipation as a syndrome of outstanding value in arousing suspicion; visible peristalsis made the diagnosis extremely probable, but only palpation of the pyloric tumour rendered it certain. He was of the opinion that a tumour could be palpated in every case of pyloric stenosis.

Dr. B. CRICHTON, referring to the large number of cases of congenital pyloric stenosis mentioned by Dr. Steen, said that he thought these figures might be rather misleading, since they gave the impression that pyloric stenosis was a common disease, which he did not think was the case. He had seen only four cases during the last six years, but he had encountered three or four of pyloric spasm. He wondered whether there was now believed to be any connexion between pylorospasm and hypertrophic stenosis. In pyloric stenosis the cardinal symptoms were vomiting, appearance of the tumour, visible peristalsis, and constipation, but last year he had seen a case in which only one symptom had been present—namely, constipation—and this was undoubtedly the most important one. He mentioned the possible value of estimating the gastric contents and of x rays in these cases, and said that he thought sometimes such observations might clinch the diagnosis. He believed that in cases where an operation was deemed necessary it should be performed as soon as possible, since waiting lowered the child's strength. He feared that a general practitioner would need great courage to perform severe in treating a child medically, since this entailed lavage twice daily; the treatment might be continued for

six or eight weeks, and if by that time there was no improvement, it might be too late to operate. Operation was undoubtedly the treatment of choice in these cases, once the diagnosis was definitely made.

Dr. J. P. SHANLEY referred to the rarity of cases of congenital pyloric stenosis, and said that in Temple Street Hospital there had not been a case for some years. Vomiting was a very common condition in children, even the projectile type, and he thought that this had not been sufficiently recognized. Visible peristalsis was a definite phenomenon, though it also was frequently present in thin babies. The tumour was pathognomonic, if it could be found. It had been reported that out of forty cases a tumour had been discovered in two only; Dr. Shanley wondered if it was justifiable to operate if a tumour could not be found, and said he thought the anaesthetic was the important part of the operation. Although Rammstedt's operation had reduced the mortality, gas and oxygen anaesthesia had diminished it still more. He suggested the advisability of giving a local anaesthetic in these cases.

The PRESIDENT, referring to the rarity of cases of congenital pyloric stenosis, said that during the fifteen years he had been pathologist at the Rotunda Hospital he only remembered having been asked once to perform a *post-mortem* examination on a suspected case of the disease. It had been reported that most of these cases occurred in the first four days of life, and therefore there should be an appreciable number in the first eight days.

NORMALITY OF TEMPERATURE AND PULSE RATE IN GIRLS.

AT a meeting of the Forfarshire Medical Association at University College, Dundee, on December 13th, 1928, with Dr. CHARLES KERR, the vice-president, in the chair, Dr. J. H. P. PATON (St. Andrews) read a paper on observations on the normal temperature and pulse.

Dr. Paton said that as medical officer of a large school for girls he had had special opportunities of observing many individuals in health, and of detecting the symptoms accompanying the onset of disease. From this work one or two facts of some clinical importance had emerged, which might enable one to define more closely than was usually attempted the limits within which the temperature and pulse might be considered normal. His observations had been made exclusively on girls between the ages of 14 and 17, and he did not claim that the results were necessarily applicable to persons of different ages and of the other sex. According to most authorities the normal temperature of the mouth was about 98.4° F., and temperatures below 98° were regarded as subnormal; these standards, he submitted, were inaccurate and misleading. For example, the temperature of convalescents, as found in actual practice, was, according to them, usually subnormal. In the majority of cases, however, the convalescent reading was of the same order as that found in health. He submitted two charts, in both of which the temperature of convalescence was below 98°, and therefore might be considered subnormal but for the fact that it differed in no way from the readings obtained from the same individuals in health. In his experience also the so-called normal temperature of 98.4° was so rare that its occurrence always warranted a suspicion of ill health. On three occasions he had had the morning and evening temperatures of a group of healthy girls recorded for a continuous period of a fortnight. The temperatures were taken orally with thermometers certified by the National Physical Laboratory, and never within half an hour after meals or within an hour of participation in active games. Altogether 108 girls were observed morning and evening, and 3,655 temperature readings were recorded. Only 25 per cent. of the readings were above 98°, and 75 per cent. were subnormal according to the usual standards. He had several reasons for supposing that even these results did not place the ruling temperature sufficiently low. In the first group of girls the records above 98° were about 10 per cent. more frequent than in the two latter groups. At the time of these first observations there was a period of very severe frost, and in the evenings the girls tended to gather round hot fires. That this resulted in some increase in the general level of the temperature seemed probable, for on the coldest night of all more than half of the girls in one house had temperatures of 98.4° or over; all admitted that they had been sitting round the fire in a very hot room. This source of possible error was avoided in later series. Secondly, a study of the charts indicated that many of the occasional readings of 98.4° or over were due to some transient disturbances of health, such as toothache. Thirdly, a few individuals had a habitually high level of temperature, and such an individual record raised the average. The following conclusions could safely be drawn from the records: (1) the normal or ruling temperature of girls aged 14 to 17 years was nearer 97.4° than 98.4°; (2) girls in whom the mean approximated to 98.4° were rare; (3) a temperature of 98.4° in the mouth was so suggestive of illness that it should not be disregarded unless no other disturbance of health could be detected.

The clinical importance of these conclusions, from the point of view especially of the early detection of the exanthemata and other infective diseases, was undoubted. Dr. Paton illustrated this point by charts from cases of measles. He held that a temperature of 98.4° warranted the isolation of a susceptible measles contact, and he had found the advantage of this interpretation of the temperature chart in the prevention and control of epidemics. A slight departure from the subject's usual temperature was by itself of no significance; the state of the pulse was the best guide in estimating the significance of a temperature on the borderline of fever. Two modifications of the heart's action were to be looked for in the young as confirmatory evidence of the pathological significance of a slight rise of temperature; these were increase in rate, and diminution or disappearance of the normal respiratory irregularity (sinus irregularity). Sinus arrhythmia, he was convinced, was invariably present in healthy children. When irregularity of the heart could not be detected upon deep breathing in the horizontal position, it could be assumed with confidence that the child was ill. In some cases the temperature and pulse rate were not disturbed though the irregularity was absent, but he could confidently assert that in these cases other evidence of disturbance of health would be present, if not at once, then in a few hours. He had made several thousand observations on this point, and on no occasion had he found sinus arrhythmia absent in a girl who was in good health. He wished to make it clear, however, that this irregularity did not always disappear in disease; the cause of its disappearance seemed to be some toxic effect upon the sino-auricular node or upon the reflex arcs governing it. When the sinus arrhythmia disappeared in disease it usually reappeared in convalescence, thus affording evidence that the toxaemia which caused its disappearance was at an end. Its reappearance was thus a valuable guide in deciding the stage at which the patient might be allowed to get up. He had found these observations on the temperature and pulse of great service in detecting the early stages of ill health in children. He had made it a rule during the first fourteen days of term, when introduction of infectious disease into the school was most liable to occur, that all temperatures were recorded night and morning, and every record of 98.4° reported at once. If after thorough examination, including observation of the pulse rate and sinus arrhythmia, any other evidence of disturbance of health was found, then the girl was isolated for twenty-four hours. He had succeeded by these means in preventing outbreaks of the exanthemata and in limiting them once they had arisen.

THE CLINICAL PATHOLOGIST AND TOXICOLOGIST IN MEDICAL PRACTICE.

AT a joint meeting of the Manchester Medical Society with the Manchester Pathological Society, at the Manchester University, with Dr. R. W. MARSDEN in the chair, Sir WILLIAM H. WILLCOX gave an address on the role of the clinical pathologist and toxicologist in medical practice.

Sir William Willcox remarked that medical practice to-day owed a very great debt to clinical pathology, biochemistry, and toxicology. It was not too much to say that the enormous advances made in medicine during the

last twenty years were mainly due to the increase in knowledge resulting from researches in these branches. On looking back it was striking to note how recent was the origin of clinical pathology; its foundations were laid by the discovery of the typhoid bacillus by Eberth in 1880, of the tubercle bacillus by Koch in 1882, of the diphtheria bacillus by Klebs in 1883 and by Loeffler in 1884, and of the pneumococcus by Frankel in 1886. For some years after the discovery of these important pathogenic organisms clinical pathology rather confined itself to the finding of the organisms in suspected cases of illness, and remained a branch of medicine more or less separate from clinical medical practice. In 1896 Widal and Durham first applied the agglutination test for the diagnosis of typhoid fever. Since that time a vast amount of study had been made of the reactive phenomena of the body to various specific infections, so that at the present day valuable diagnostic tests existed for a large number of diseases. The studies in immunity had provided medical practice with some of its most valuable therapeutic remedies, such as diphtheria and tetanus antitoxins as types of passive immunization, and the various forms of vaccine therapy, such as typhoid vaccine, whereby active immunity was induced, either for prophylactic purposes or for the treatment of active disease. Refinements in bacteriology had enabled diseases to be differentiated and subdivided. Thus clinical typhoid fever had been subdivided into true typhoid and paratyphoid fever, the organism of the latter being differentiated by Gwyn in 1898. Paratyphoid fever itself had been subdivided into paratyphoid A and B by the work of Schottmüller in 1900; and a further variety, paratyphoid C, had been defined by Hirschfeld in 1919. More recent advances in cultural bacteriology had shown that a number of non-lactose-fermenting organisms of the paratyphoid group existed, which might cause fevers of the enteric type; examples of these were the *Bacillus asiaticus* and *pseudo-asiaticus*, the *Bacillus faecalis alkaligenes* and its pseudotype, the bacillus of epidemic jaundice, and the *Bacillus morgani*. The term "parenteric organisms" might conveniently be applied to these. These organisms were *undoubtedly pathogenic, and their presence could not be overlooked* as of no importance. Attention had been called to the prevalence of mixed infections by the paratyphoid group of organisms; thus, a case of typhoid or paratyphoid infection might reveal in the intestine one or more of the parenteric organisms. The Widal agglutination test for paratyphoid A and B, or even for true typhoid, might be affected by the presence of such a parenteric infection. It was well known that this test might on rare occasions be negative throughout a severe attack of true typhoid or paratyphoid fever. In diphtheria the recent discovery of the intradermal Schick test had enabled an existing immunity to be diagnosed and the necessity or not of giving antitoxin to an exposed person to be clearly indicated. In scarlet fever the intradermal Dick test had a similar value. In this disease a valuable aid to diagnosis during the rash period had been provided by the Schultz-Charlton intradermal serum test, where a definite blanching indicated a positive diagnosis. The production of immunity by vaccine or serum therapy in a person suffering from an acute or chronic infection required the closest clinical observation. Sensitization might easily result from incorrect uses of biotherapy, and harm instead of good result. Studies in haematology had proved of the utmost value and guidance in the diagnosis and treatment of various infective conditions. The recent discovery of the value of liver therapy in pernicious anaemia had largely followed haematological studies of this disease, and blood examinations were of great value in indicating the beneficial effects of treatment, and also in the diagnosis of early cases suitable for treatment. Biochemistry had expanded remarkably; chief among the recent advances had been the methods of estimating the function of such organs as the kidney, liver, and pancreas. The treatment and management of cases of renal disease and diabetes were mainly dependent upon the blood estimations for urea and sugar respectively. Toxicology had furnished recent instances of striking advances in knowledge. For example, improved methods of analysis had shown that arsenic might exist in minute amounts normally in the body, and that the urine of a normal person, not exposed to arsenic in any way, might contain up to 0.1 mg. of arsenic in a litre. Similarly, recent researches in America had shown that lead was commonly present in normally healthy persons who had not been exposed to lead in any way. The amounts found corresponded approximately to about 0.07 mg. in a litre. Sir William Willcox urged that at the present time the fullest advantage should be taken of advances in knowledge, and every case be submitted, where possible, to those investigations which might be of value in diagnosis and treatment. The investigations should be in the definite direction of furthering accuracy in diagnosis, unnecessary routine investigations being deprecated. The closest co-operation and consultation between the physician and the clinical pathologist or toxicologist were essential for a proper interpretation of the results. The patient, and not the disease, had to be treated, and therefore the clinical pathologist, in order to achieve success, should not treat cases except in association with a clinical colleague.

RECENT WORK ON ACUTE INFECTIOUS DISEASES.

AT a meeting of the Windsor and District Medical Society on February 20th, Dr. J. D. ROLLESTON read a paper on some recent work on the acute infectious diseases, dealing in particular with chicken-pox; diphtheria, measles, scarlet fever, and vaccinia.

Dr. Rolleston said that as regards the relationship between herpes zoster and varicella, he had until recently been inclined to side with Comby, the principal representative of the dualist school, who regarded the association of the two diseases as a mere coincidence, but his belief had been shaken by the case of a young woman who had had an attack of chicken-pox followed by facial paralysis. On investigating the source of infection he had learnt that a younger sister had had a few spots some weeks before, and examination of the child revealed the typical pigmented scars of chicken-pox on the trunk. Further inquiry elicited the fact that the father had had an attack of cervical herpes zoster about a fortnight before his little girl's eruption appeared. *Unlike Trousseau*, who said that no physician had ever seen a patient die of the disease, Dr. Rolleston, in the course of twenty-eight years' fever practice, had met with four fatal cases of varicella. Two were examples of the bullous and one of the gangrenous type, while the fourth was complicated by pneumonia in an alcoholic man aged 62. Allusion was made to the prevalence of diphtheria of a malignant type in various European countries, including different parts of Germany—particularly Berlin, the Rhine district, and Breslau—Budapest, Padua, and Barcelona. The malignant character of diphtheria on the Continent was in striking contrast with the generally benign type prevalent in London, where the mortality in 1927 in the Metropolitan Asylums Board hospitals was only 4 per cent., the lowest hitherto recorded in the history of the Board. Dr. Rolleston then discussed some of the aberrant localizations of diphtheria, such as diphtherial whitlow, endometritis, and urethritis, and the present position of prophylaxis and treatment. Dealing with the prophylaxis of measles by injection of convalescent serum, which he described as one of the most important preventive methods in medicine, he said that it was specially indicated in the case of ill-nourished rickety children living in insanitary dwellings, but he did not consider it necessary in hospitals with a hygienic environment or in well-to-do families, since in his experience measles contracted in such surroundings always ran a mild course. He was not in favour of the active immunization of nurses against scarlet fever as he was in the case of similar inoculation against diphtheria. Not only was scarlet fever much less serious, but its incidence among them was naturally much lower than that of diphtheria. He spoke highly of the value of anti-scarlatinal serum, but reserved it for cases of any degree of severity, so that in the course of three years he had employed it in only 320 cases out of over 3,000 scarlet fever patients admitted to his hospital. He had been much impressed by its value in septic cases, provided it was used early. In conclusion, Dr. Rolleston dealt with recent work on the nervous sequels of vaccination.

Reviews.

DISEASES OF THE LIVER, GALL-BLADDER, AND BILE DUCTS.

ROLLESTON'S *Diseases of the Liver* was first published in 1905, and immediately became the leading textbook on the subject in the English language. A second edition appeared in 1912, and now a third has been called for. In the seventeen years which have elapsed since the publication of the last edition an enormous amount of work has been done on all aspects of hepatic physiology and pathology, and it is therefore not surprising that the original author, Sir HUMPHRY ROLLESTON, should have felt it desirable to seek the help of a younger colleague in the arduous task of revision, and he has made the excellent choice of Dr. J. W. McNEE, who is already so well known for his original investigations in this department of medicine. The book will accordingly, no doubt, be known in future as Rolleston and McNee's *Diseases of the Liver, Gall-bladder, and Bile-ducts*.[1]

Owing to the large amount of new material which has had to be included, the present edition is longer than the last by more than seventy pages, but the number both of coloured plates and of illustrations is less, although many of the latter appear for the first time. Amongst the entirely new matter there come first sections on the anatomy and physiology of the liver, in the latter of which a clear and succinct account of the metabolic and other functions of the organ are given. As the authors point out, some knowledge of the latest work on liver physiology is necessary for the proper understanding of changing conceptions of hepatic and biliary disease. The section on functional diseases of the liver and tests of hepatic function contains a full description of the biochemical and other tests for liver efficiency, but we could have wished for a clearer expression of the authors' views as to the absolute and relative values of the different tests. We notice, too, that in this section, despite its title, there is no account of functional disorders of the liver such as appeared in the last edition; indeed, the term "biliousness" is nowhere mentioned, and has disappeared from the index. The authors may have had some good reason for this omission, but it seems regrettable; and we should have liked also to have heard their views on the possible relation of disordered hepatic function to such conditions as migraine and to the acidosis of childhood. The section on jaundice has been practically rewritten to bring it abreast of present knowledge, and no fuller or clearer account of the varieties and modes of origin of this symptom could be desired. A comparison of it with the corresponding section in the last edition will show how revolutionary the change of view on many aspects of the subject has been. Atophan and its allies, however, are not mentioned among the possible causes of toxic jaundice. Another entirely new chapter describes the radiological diagnosis of diseases of the biliary tract, and deals fully and critically with the new methods available and their diagnostic value. An appendix to the book is devoted chiefly to an excellent description of the van den Bergh reaction, of which Dr. McNee has had so much experience.

These are the sections in which the new edition chiefly differs from its predecessor, but throughout the whole book many minor changes have been made. Weil's disease is definitely identified as spirochaetosis icterohaemorrhagica, of which a very complete description is given embodying all the new work that was done upon this disease during the war and afterwards. Acute yellow atrophy is now spoken of as "acute and subacute necrosis of the liver," and the authors foreshadow other changes in nomenclature which may be necessary before long. They play, indeed, with the idea of reclassifying hepatic disease on the basis of "hepatitis" (a conception for which there is much to be said), but they have wisely decided in this matter to make haste slowly. Meanwhile, this new edition is a monument to the learning, diligence, and clinical experience of the writers, and a credit to British medicine. It is both exact and exhaustive; indeed, if we might venture to say so, it is almost too exhaustive—more than 120 pages, for example, are devoted to portal cirrhosis alone—for the authors have been so careful to do full justice to the work of others, and to leave no facet of the subject unexamined, that it is a little difficult in places to see the wood for the trees, and a less high-power view would have been easier to grasp. As a standard work of reference, however, the book deserves, and will no doubt enjoy, an even greater measure of success than it has had hitherto.

RADIUM TREATMENT OF CANCER.

THE publication of Mr. STANFORD CADE'S important textbook[2] should go far to dispel the illusion that this country still lags behind the Continent in the treatment of cancer by radium. A number of works dealing with individual aspects of radium therapy are available to the English reader; Mr. Cade's book, however, is the first in English to cover the whole subject-matter and to present it from the practical standpoint of the operating surgeon. Whatever the previous convictions of the reader, this book will certainly make him realize that there is much to be said in favour of using radium in the treatment of cancer of certain regions. In particular, the results of radium therapy in carcinoma of the tongue, larynx, breast, and uterus appear to equal if not surpass those procured by surgical methods. The technique now employed in treating carcinoma of the tongue and buccal cavity seems definitely to hold out a better hope of success than any other means. The difficult question of how to deal with the lymphatic glands is admittedly unsettled, though Mr. Cade leans towards a Crile's operation, followed by prolonged irradiation of the neck for two weeks, or in some cases longer, by means of a Columbia paste collar. Whereas formerly the method of choice was to irradiate with large doses for short periods, the tendency to-day, in the treatment of most cancers, is to rely on small doses for very long periods. The results of this modern technique in the treatment of cancer of the breast are already such that the surgeon must seriously consider whether radium therapy does not offer at least as good prospects of cure as Halsted's operation. The gynaecologist also will have to decide whether, in cases of carcinoma of the cervix uteri, radium does not give better results, and with practically no risk, than he may expect to obtain from Wertheim's operation. Time and further work alone can settle these questions, but certainly Mr. Cade, and such workers as Dr. Malcolm Donaldson, make out a very strong case for radium.

At this moment, when so many appeals are being made to the public to buy radium for the hospitals, a technical work, such as Mr. Cade's, will prove of inestimable value, and we cannot recommend too strongly that every surgeon who has hitherto not had the opportunity to employ radium should read this volume very carefully. Although a book, however good, will not of itself give the reader skill in the administration of radium, it will at least put him on the right lines and save him from disaster.

The book is profusely illustrated by coloured plates and drawings, which help to explain the often rather elaborate technique of modern radium therapy.

[2] *Radium Treatment of Cancer.* By Stanford Cade, F.R.C.S. London: J. and A. Churchill. 1929. (Roy. 8vo, pp. viii + 153; 47 figures, 15 plates. 15s.)

ANTE-NATAL CARE.

ANTE-NATAL care now plays so prominent a part in midwifery practice that a book[3] by Dr. W. F. T. HAULTAIN and Dr. E. C. FAHMY, the first devoted solely to this subject to be brought to our notice, is sure of a wide welcome. That it comes from the Edinburgh school, where ante-natal work was started and developed by the late

[3] *Ante-Natal Care.* By W. F. T. Haultain, O.B.E., M.C., M.B.Camb., F.R.C.S.Ed., and E. Chalmers Fahmy, M.B., F.R.C.S.Ed. With a foreword by Professor R. W. Johnstone, C.B.E., M.D., F.R.C.S.Ed. Edinburgh: E. and S. Livingstone. 1929. (Cr. 8vo, pp. xi + 113. 1 plate. 5s. net.)

J. W. Ballantyne, gives it a special claim to our consideration. The book is handy in form, with little more than 100 pages; it must therefore be regarded as an outline of essentials only. The first of twelve chapters gives a short account of the arrangement and working of the Edinburgh Ante-natal Clinic, including reproduction of the case-cards and a photograph of the examination room—all of it valuable to those who may have charge of similar clinics elsewhere. All patients at their second visit are submitted to the Wassermann test; it is admitted, however, in the final chapter that this is not an absolute criterion during pregnancy, and that a negative result cannot be regarded as reliable. Among the chapters specially calling for notice there is one on the examination of the patient in which not only are the methods of diagnosing positions and presentations clearly described, but also the rectifications of posterior positions of the vertex and external version in breech presentations are considered. The chapter on albuminuria, eclampsia, and chronic nephritis is also good, though for a work of this size a disproportionate amount of space seems to be devoted to the treatment of the patient in convulsions. The chapter on pain in pregnancy is useful, and the concluding one on venereal diseases gives an excellent and practical summary of diagnostic and therapeutic methods.

In its obstetrical teaching the book is sound and can be generally recommended. Some readers, however, will feel a little disappointed at the restricted view here given of the ante-natal field, for the authors have presented merely an abstract of those parts of obstetrics which are applicable to their subject, and devote sparing attention to the educational and social aspects. In matter and style the book is rather reminiscent of the formal treatise on midwifery, and for this reason it conveys less than we had hoped of the spirit of ante-natal work. The authors would have done better, we think, if they had given less information about the treatment of eclampsia and placenta praevia, which can be readily obtained elsewhere, and had entered more fully into minor troubles and the fears of the pregnant woman, which pass without notice in textbooks and yet are often difficult to dispel.

DISEASES OF THE BRAIN.

THE section of *Nouveau Traité de Médecine et de Thérapeutique*[4] devoted to brain diseases opens with a chapter of great interest which, under the heading of "*Commotion cérébrale*," describes the effects of physical violence upon the intracranial contents. The writer is insistent that cerebral commotion is not a condition of slight or ingravescent concussion, but may exist independently or in association with this condition. It is marked by symptoms indicating a varying degree of paralysis of all the nervous mechanisms of the brain, begins universally with loss of consciousness and medullary inhibition, and, if not fatal in this stage, gradually progresses through a condition of subcoma, still with completely generalized signs indicative of paresis, to complete recovery, even retrograde amnesia being rare. If any signs are present of localized defects these are due to concomitant contusion. The cerebro-spinal fluid may be under great pressure and albuminous, but is never haemorrhagic or xanthochromic. This condition, he says, is caused by an *ébranlement transmis* in which the skull vibrates as a whole, giving a perfectly generalized shock to its contents. The difficulty of accepting this explanation arises from the fact that the force applied to the skull is always directional—always applied to one aspect—and, however instantaneous, will lead to a distortion of the cranium maximal along the corresponding diameter; and even if the skull could be subjected to a perfectly generalized sudden pressure and release its physical conformation, would lead to a perfectly definite deformation maximal along one plane. Moreover, the rarity of retrograde amnesia in commotion, and its admitted frequence in contusion, alone is a strong argument in favour of our regarding contusion as resulting from a commotion which has been sufficiently severe to result in not immediately recoverable lesions at the places where the yielding has been maximal.

The second chapter deals in a methodical way with the pathology and symptomatology of cerebral haemorrhage, including a valuable description of the *état lacunaire* and basal haemorrhage. The author supports Charcot's claims for one particular branch of the lenticulo-striate artery as the artery of cerebral haemorrhage, although the work of Foix and Hilleman among others has recently discredited this view. Perhaps undue insistence is laid upon the suddenness of onset of the symptoms of cerebral haemorrhage and too little upon the almost invariable prodromal condition, but these defects are amply compensated for by the clear and valuable description of syndromes resulting from haemorrhage into the mid-brain. Cerebral syphilis is described in a chapter to itself as distinct from those on general paralysis and cerebral softening, an arrangement which necessitates much repetition but which is difficult to avoid. All these are clearly and exhaustively dealt with, and their information is fully up to date. There remain for description the chapters on cerebral tumours and cerebral abscess. The usual classification is adopted and the description of the characteristics of each type of neoplasm is clear and complete. The explanations provided for those signs usually held to be indicative of increased intracranial pressure are not clearly separated from those peculiar to the site in which the tumour is found.

This work can hardly be considered a complete and exhaustive examination of the subjects with which it deals, but within the scope provided for discussion the matter is well arranged and clearly set forth.

THE FLUORESCENT SCREEN AS AN AID TO TREATMENT OF FRACTURES.

IN a monograph[5] on this subject Dr. RADUTZESCO, a Rumanian who has served as a foreign assistant in the clinic of Professor Pierre Duval in Paris, describes the systematic diagnosis and treatment of fractures of the wrist and ankle with the help of x rays and the fluorescent screen, and illustrates his work with a number of reproductions of x-ray plates. He describes the "radioscopie shovel" of Dr. Henri Béclère. (It would have been better to call a spade a spade, for this appliance is far more like a spade than a shovel.) The precautions necessary to protect the surgeon and his assistants from the effects of the rays are also described. The screen should be covered with lead glass at least 10 mm. thick. The other precautions are those now usual with x-ray workers. The plaster splints of Hennequin, Delbet, and Quénu are described and recommended, and eleven cases of fracture of the lower ends of the forearm and leg bones, and one of the middle of the shaft of the humerus, are very fully described and illustrated by 33 plates, the figures showing the conditions before, soon after, and weeks after the injuries. The author sums up the results of his experience in a number of "Conclusions," which are rendered in five languages besides the original French. The effort of the translator into English is not altogether successful. "Intervention sanglante" is not adequately rendered by "fleshy operations," and in another paragraph the author's meaning is badly distorted.

We think this is likely to be a useful work, although it seems almost a counsel of perfection to suggest that such elaborate proceedings should be made the routine for a class of cases that are adequately treated generally by the ordinary use of x rays, provided that the surgeon is experienced and instructed in sound principles. In a hospital treating many fractures it would be difficult to spare the time and space necessary for all these radiographs and screenings. There is a table of contents, but no index to this book.

NOTES ON BOOKS.

No. 2 of the Memoir Series of the London School of Hygiene and Tropical Medicine contains an account of researches conducted during 1924 and 1925 in Polynesia and Melanesia[6] by Dr. PATRICK A. BUXTON. These have reference principally to filariasis, but notes are appended on other diseases occurring in Samoa and other archipelagos, more especially on yaws, Samoan conjunctivitis, and helminthiasis; a chapter is added on the customs of the Samoans of a hundred years ago, and of the foreign influences which have affected them, and their results. In the examination of cases of filariasis the author considers that the presence or absence of six physical signs should be regularly recorded—namely, enlargement of the superior inguinal glands, the inferior inguinal glands and the epitrochlear glands, the enlargement or fibrosis of the epididymis or testis, and the presence of hydrocele. Enlargement of the epitrochlear gland is the commonest physical sign of filariasis; it is that most closely correlated with the presence of micro-filaria in the blood, and will not improbably be used in Oceania in the same way that spleen rate is used by the malariologist. It is, however, rare in some regions, and cannot, therefore, be of general utility throughout the tropics. Hydroceles are common in Oceania; they are mostly bilateral, and generally caused by filariasis, though whether due to blocking of lymphatics, to the production of a toxin, or to secondary infection is not clear. With regard to elephantiasis, assuming that the filaria is an essential antecedent to its development, the exact position of the parasite as an etiological agent is still obscure; whether it is an immediate cause or an adjuvant is not known, and owing to the impossibility of obtaining *post-mortem* examinations the pathology of elephantiasis could not be studied in Oceania. With regard to the vector of the non-periodic filaria in Fiji and Polynesia there seems to be little doubt that it is *Aëdes variegatus*. Myositis, suppurative and non-suppurative, which has generally been regarded as due to filaria, was studied in thirty-two cases; the author concludes that it is a staphylococcal pyæmia of unknown origin, characteristic of the damp tropics. The volume is illustrated with many excellent photographic plates.

When we reviewed the fourth edition of Professor C. P. EMERSON'S *Essentials of Medicine* (June 11th, 1921, p. 858) we commended it as a clearly written book for nurses and for students beginning a medical course. In the eighth and considerably revised and enlarged edition,[7] recently issued, the author, by eliminating from his account all that is accidental, rare, or disputed, once more succeeds in presenting in an interesting manner the general outline of clinical medicine, leaving it to the student as he grows in knowledge and experience to fill in the details.

The *Minutes of the General Medical Council and of its Various Committees*[8] for the year 1928 have now been issued, with seventeen appendixes, in a volume which includes the customary reports of the two sessions of the General Medical Council and of its Executive Committee, of the meetings of the English, Scottish, and Irish Branch Councils, and of the Dental Executive Committee. The appendixes comprise memorandums on the training of medical practitioners and midwives, reports of the Education, Dental Education and Examination, Public Health, Pharmacopœia, and Examination Committees. The *General Index* to the Minutes of the General Medical Council and of its Executive and Dental Executive Committees, and of its three Branch Councils from 1903 to 1928, and relating to volumes xl to lxv, also just issued, follows the plan of the previous issue in grouping the references under each head in chronological order, in indexing each subject under two or more headings, and in supplying a sufficient number of cross references.

The British Journal Photographic Almanac[9] for 1929 should be welcomed by photographers of all types, from the amateur "dabbler" to the trained professional. The editor, Mr. GEORGE E. BROWN, contributes an interesting article on the use of the camera in the detection of crime, and Mr. T. J. L. Bentley deals exhaustively with action photographs and their making. The volume includes a series of excellent reproductions of fine photographs from many parts of the world. Recent developments in photography are fully discussed.

[9] *The British Journal Photographic Almanac, 1929.* Edited by George E. Brown, F.I.C. London: H. Greenwood and Co., Ltd. 1929. (4½ × 7¼, pp. 758; illustrated. 2s. net.)

Volume xxii of the *Transactions of the Medico-Legal Society*[10] covers the proceedings of that body during the session 1927–28. Among the papers is one by Professor Louise McIlroy on "Influence of parturition upon insanity and crime," which provoked an interesting discussion on the medico-legal aspects of infanticide. Drunkenness was the subject of two communications, one relating to "pathological drunkenness" as a defence of insanity at a murder trial, and the other discussing drunkenness and civil and criminal responsibility. The papers by Dr. Gerald Slot on "Pain in its medico-legal aspects," and by Dr. John Glaister, jun., on "Hair—considered medico-legally," should also be mentioned.

Dr. R. FORTESCUE FOX'S *British Spas and Climatic Health Resorts, 1929*,[11] which is incorporated in the *Medical Directory*, has been published separately in pamphlet form. In addition to notes on the choice of waters, sea bathing, etc., detailed information is given about all the principal health centres in Great Britain, and also certain New Zealand spas.

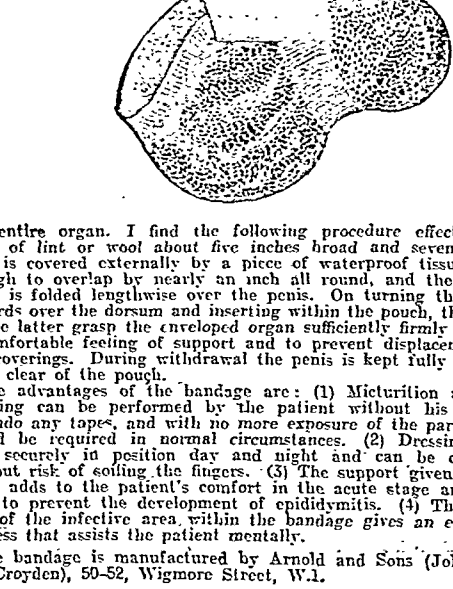
PREPARATIONS AND APPLIANCES.

A SUSPENSORY BANDAGE FOR USE IN GONORRHŒA.

DR. A. GARDNER (R.M.S. *Empress of Scotland*) writes: In the treatment of gonorrhœa in the male, I have found the following suspensory bandage much appreciated by patients as a comfortable support, and as a convenient and cleanly means of holding dressings in position.

The bandage differs from the ordinary suspensory bandage in having a separate pouch for the penis in addition to the usual support for the testicles. This pouch is suspended from the pubic attachment of the bandage, and is provided with an adequate elastic-bound opening at the root of the penis, whereby the latter can be withdrawn for the purpose of micturition or changing of dressings. To ensure that the dressings will be securely held in position within the pouch and to enable them to be handled without risk of the fingers coming into contact with discharge, it is essential that they be large enough to envelop



the entire organ. I find the following procedure effective. A piece of lint or wool about five inches broad and seven inches long is covered externally by a piece of waterproof tissue large enough to overlap by nearly an inch all round, and the double layer is folded lengthwise over the penis. On turning the edges inwards over the dorsum and inserting within the pouch, the walls of the latter grasp the enveloped organ sufficiently firmly to give a comfortable feeling of support and to prevent displacement of the coverings. During withdrawal the penis is kept fully covered until clear of the pouch.

The advantages of the bandage are: (1) Micturition and redressing can be performed by the patient without his having to undo any tapes, and with no more exposure of the parts than would be required in normal circumstances. (2) Dressings are held securely in position day and night and can be changed without risk of soiling the fingers. (3) The support given to the penis adds to the patient's comfort in the acute stage and may help to prevent the development of epididymitis. (4) The isolation of the infective area within the bandage gives an effect of tidiness that assists the patient mentally.

The bandage is manufactured by Arnold and Sons (John Bell and Croyden), 50–52, Wigmore Street, W.1.

Nova et Vetera.

HERRINGS AS FOOD AND PHYSIC.

THE announcement in the press that an "eat more fish" campaign is to be inaugurated by those interested in the catching and marketing of fish recalls a similar attempt made 150 years ago. By the middle of the eighteenth century fishing on the east coast had fallen into a parlous condition. It had been decaying gradually for a hundred years previously. Invaded by foreigners, chiefly Dutch, with larger boats and better gear, the all-important herring fishery had ceased to be one of the great sources of English wealth. The frequent wars with Holland were due in large part to the difficulties and jealousies arising out of the herring industry. In the year 1748 a serious attempt was made to revive the fishery, which could be done only by the provision of a large sum of money to subsidize the building and equipment of suitable boats. A bill was accordingly passed by Parliament announcing (1) that as the fishery was of great advantage to the trade and navigation of the kingdom all possible impediments to it should be removed; (2) that a bounty of 30s. per ton was to be paid to all new vessels between twenty and eighty tons suitable for, and employed in, the fishery; and (3) that a Company of Adventurers be formed with power to raise a capital sum of £500,000, interest at the rate of £3 10s. a year being guaranteed to the proprietors for a period of fourteen years. At a meeting held in the City the names of a number of gentlemen were proposed to the Crown for nomination as officers in the Charter. In addition, certain local committees were formed at outports subscribing the sum of £10,000. The Prince of Wales consented to be the Governor of the Company.

It is probable that the appeal for money did not meet with a satisfactory response, for a need appears to have arisen for an "eat more fish" campaign. In the year 1752 a surgeon named James Solas Dodd published a book of 175 pages, designed to arouse public enthusiasm in favour of herring as food and physic. The book opens with an introductory bibliography of the fish from ancient times, showing the esteem in which it had been held from the reign of Philip of Macedon onwards. There follows an exhaustive account of the natural history of the fish, with the fullest anatomical details, these being supplemented by an account of their migration and the methods of catching and curing them for the market. Then, however, comes the real purpose of the book, to discuss the "cold temperament" of the herring, and its freedom from harmful "heating" qualities.

From the author's numerous recipes for the preparation of the herring as food we cite the following.

To Stew Herrings.

When your herrings are scaled, washed and the fins cut off, put them in a stewpan, with no liquor, but a quarter of a pint of white wine, some mace, whole pepper and salt. When they are half stewed, put in some thick cream, and a little piece of butter dipped in flour; when that is melted, put in some oysters with their liquor; keep them often shaken till the fish and oysters are enough, or that the oysters will break; squeeze in a little lemon, give them a scald, and pour them into a dish.

To Roast a Brace of Herrings.

Take two very large herrings washed very clean, strew a little salt, hang them on the spits of a tin-oven. Throw away all the water that comes from them for the first half-hour; then throw on a little nutmeg, mace and cloves, beat fine, and a little salt; flour and baste with butter and crumbs of bread. When one side is done turn the other. Then have ready some anchovy and melted butter, some of the liver of the fish boiled and bruised fine; mix it well with some butter and two yolks of eggs, strain through a sieve, and put them into a saucepan again with a few shrimps, or pickled oysters, the juice of a lemon, and a little red wine. Put it into the pan that you put your herrings in, and stir all together; then pour it again into the saucepan, keep it stirring, let it boil, and then serve it up, garnished with pickled barberries.

A Fricasse of Rocs.

Take a quantity of soft roes blanch'd, cut them into dice; put a lump of butter in a stew-pan, and toss it up with an onion cut small. After that put in your dice, and give them two or three tosses; this done, put a little flour over them, moisten them with a little fish broth, season with salt, pepper, sweet herbs, and fine spice, and let them stew gently. Being done, thicken it with volks of eggs, parsley cut small, and a dash of vinegar, served up hot.

Note that pickled roes will do as well steeped in water to unsalt them, and omitting salt in the seasoning.

Not content with the use of herrings as food the author proceeds to consider their medicinal value. He quotes Dr. Fuller on feet cataplasms, and supplies an explanation of how these act. Herring cataplasms fall into the acrid and stimulating category, being indicated when the spirits are oppressed, stupid, and sluggish, as in soporose cases. Here is one of his prescriptions:

A Cataplasm of Herring.

Take white briony root new digged up (or if it be dried, then the powder of it) two ounces; black soap three ounces, pickled herrings (or anchovies) four ounces; salt one ounce and a half; and mix. It is to be bound to the soles of the feet, and changed every twelve hours, and is chiefly used where the febrile matter assaulting the head, and oppressing the spirits, causes a stupor or sleepiness.

Various authors are quoted who recommend salt herrings as a remedy for plague; herring, dried and powdered, is alleged to open obstruction of the urinary passages; the ashes of burnt herrings serve as a lithotriptic; used in clysters the herring is held to be a remedy in sciatica and dropsies. The oil is excellent in the treatment of cramps and convulsive contractions, while an elixir of the bones operates in febrifick cases by stimulating sweat and urine.

Here are a few of the prescriptions in which herrings are used, with the diseases to which they are appropriate:

Extract of Herrings.

Take six pounds of fresh herrings, four ounces of salt of tartar, and put into a matrass, and pour on six pints of rectified spirits of wine; let it stand in infusion in a bath heat for four days, then decant, and pour on six pints more, and let it infuse till it will give no more tincture. Put these tinctures together and filter them, and exhale the humidity in a sand heat, till the matter be left at the bottom the thickness of honey. Half a scruple of this taken for a dose in the form of a bolus is of great service in all urinary obstructions, and joined to other deobstruents may be of great utility in other obstructions.

A Cleansing Ointment of Herrings.

Take fresh herring twelve pounds, oil of olives the same quantity, boil three hours and strain off. Then add gum euphorbium, powder of white hellebore, each four ounces. Gum olibanum, gum sarcocol, and gum elimi, each half a pound; yellow wax, two pounds. Melt and make an ointment.

This is a medicine of great service in the itch and all cutaneous eruptions, and may be conveniently joined with an eighth part of mercury; allay'd with turpentine for leprosies, being warily used.

Essence of Herrings.

Take twenty soft roed herrings, cut them in pieces, and put into a cucurbite with a quart of spirits of wine, and eight ounces of white wine. Let them digest in horsedung for six weeks, and pour off and filter for use.

This is a diuretic, and may be taken to the quantity of thirty drops in a proper vehicle.

A very long recipe describes how herrings can be distilled "after the manner of vipers," the results being (1) a volatile salt which is a high sudorifick and deobstruent, of excellent service in maligunant fevers and very prevalent in epileptic cases, (2) a fetid oil to be applied to contracted sinews, and (3) a spirit with the same virtues as the salt.

Various parts of the fish have their several uses: The gills burnt to powder are accounted a specifick in, and a preservative from epilepsies. One that was troubled with a fistula at the lower orifice of the stomach, was cured by swallowing every morning for a month, a herring's heart. The liver dried to powder, and mixt with honey is a present cure for toothache. The gall mixt with honey and taken cures dysentery. The spawn put in a linen cloth and applied, is excellent in the piles. The soft roe distill'd produceth a water exceeding frog's spawn water for a cooling cosmetick, is good in burnings, redness in the face, and eruptions of the body. The oil of the roes is good for deafness, mixt with eels gall and dropped into the ear.

Perhaps the most curious of all the nostrums quoted is that in which herrings assist in the preparation of a general anaesthetic.

Take the oil pressed out of fresh herrings, a pint, a boar's gall, juices of henbane, hemlock, aifel (that is, the little house leek) lettuce and wild cat-mint, each six ounces, mix them together, and boil them well, and put them into a glass vessel well stopt. Then take three spoonfuls of the above and put into a quart of warm ale and let the person who is to undergo any operation sit before a large fire, and drink of this by an ounce at a time, till he falls asleep, which sleep will continue during the space of three or four hours; and all that time he will be insensible of any thing done to him.

The author is a little shy of this prescription and rather doubts whether it would render a man entirely insensible to pain, and gives an amended version of his own as a hypnotic, a drachm to be rubbed into the pulses of the wrist to procure sleep.

The work concludes by an appeal to people to invest in a scheme, which is no South Sea bubble, but guaranteed by the State. Therefore under such appearances of success let no one fear a loss, but cheerfully contribute to the raising of this undertaking to the acme of perfection; then we shall rejoice and sing; then again the entire balance of power will be in British hands, and then we may sit down each man under his own vine and his own fig tree, and fear no invader, since after that period should any be so daring as to shock our peace, we could draw from our busses a train of hardy veterans, true British seamen, who alone could guard that island they support.

MARK R. TAYLOR, M.R.C.S., L.R.C.P.

CONGENITAL DISLOCATION OF THE HIP.

LECTURE BY MR. H. A. T. FAIRBANK.

ON the afternoon of February 28th, in the Medical Building of the University of Liverpool, Mr. H. A. T. FAIRBANK delivered the Lady Jones Lecture in orthopaedic surgery, his subject being congenital dislocation of the hip, with special reference to its anatomy.

Changes in the Acetabulum.

Mr. Fairbank began by describing the anatomy of the dislocated hip, basing his description on a study of 35 museum specimens, 50 open operations, and the literature of the subject. The primary anatomical fault, he said, was deficient growth of the upper acetabular margin, to which all other changes were secondary. The malformation involved the cotyloid ligament, the cartilage, and the bone. Before many years the acetabulum became triangular, with the apex upwards and backwards; the margins were fairly straight, sharp, and even undercut. In dry specimens the socket was surprisingly deep, but the floor was flat; in the fresh state it was largely filled by cartilage and fibro-fatty material. The ilium presented a wavy anterior margin, with a deep notch for the psoas tendon. A false acetabulum, which might be a shallow pond considerably larger than the femoral head, and suggestive of decided mobility of the latter in all directions, was usually seen on the dorsum ilii. The floor might present flat-topped bosses with the margin raised, even to the extent of forming a deep cup with an eburnated surface, resembling, in fact, a typical osteo-arthritic socket. In a bilateral case these changes might occur on one side only. A raised hollow facet might represent the false joint. The surface of the bone behind the true acetabulum was usually modified; owing to the increased strain thrown on this region of the bone by the capsule, it might be markedly roughened or thickened to form a rough ridge; or it might present a facet, usually single, corresponding to a similar facet on the lesser trochanter. This facet, which lay within the joint cavity, with the capsule attached to its posterior margin, might overlap the acetabulum to a considerable extent.

The False Joint.

The head of the femur was usually small, and it might be wedge-shaped, conical, mushroomed, eroded and lipped, or largely worn away. The angle of the neck was usually normal, though coxa vara and coxa valga sometimes occurred. Ante-torsion of the head and neck was usually present, but rarely extreme. The neck might present a polished facet, more commonly in front, the result of friction against the capsular sling. The lesser trochanter in adults might be well formed as in children, hardly be visible, or be capped by a facet with a lipped margin. The capsule was stretched upwards by the head, and the cavity became hour-glass shaped, with an isthmus in the middle, which was accentuated by the psoas tendon which crosses it. In the floor of the false joint the capsule blended with the periosteum and became fibro-cartilaginous; it was much thickened in front and below, and particularly behind. The ischio-capsular band, which was very strong, arched over the neck to join the fibres from the front of the acetabulum, thus forming a *capsular sling*. The ligamentum teres was often absent in older cases and after forcible treatment; very rarely it interfered with complete reduction. The joint cavity always extended backwards over the ischium, a vertical fold of the synovial membrane sometimes marking the separation of this posterior extension from the true acetabular portion. Also present in some cases, and situated just above the upper margin of the joint, was a horizontal fold which piled up on the upper margin if the femur was pulled down as, for example, in attempted reduction. In adult specimens this fold might be prominent, the isthmus being displaced outwards towards the femur. It partly, and even completely in some cases, separated the upper portion of the cavity containing the head from the other two below.

Action of Muscles.

Of the muscles, the adductors, hamstrings, and rectus were short, but only the first interfered with reduction. The sciatic nerve was short, but could be relaxed by flexion of the knee. Injury to this nerve during reduction was due to bruising rather than stretching. The psoas tendon passed horizontally backwards and outwards to the femur, and acted as a sling supporting the pelvis. The glutei were not much shortened, but they were weak on account of the reduction of their area of origin. They abducted the femur and held it to the pelvis. The obturators and associated muscles ran obliquely upwards to the femur, and acted as important slings for the pelvis.

The pelvis, said the lecturer, was therefore supported on the femur by the thickened bands in front, but particularly by the "capsular sling" over the neck, assisted by the psoas in front and the obturator group of muscles behind. The characteristic gait was due to the weak abductor muscles acting at a mechanical disadvantage, since the levers, formed on the one hand by the head and neck, and on the other by the ilium, were shortened, while the distance from the head to the midline, in which the body weight acted, was increased. Other possible factors were the antero-posterior instability of the head and the adductor action of the obliquely running obturators which must contract to support the pelvis. Furthermore, the weak abductors (glutei) not only acted at a mechanical disadvantage, but had to resist the adductor pull of the obturators.

Pain and increasing disability in adolescence or adult life might be due to muscle strain, but if severe they were due to arthritis. Arthritis might be infective in origin or a typical osteo-arthritis; a villous arthritis had been described. The prognosis of the untreated case was not hopeless, and many patients reached middle life without serious disability.

Treatment.

In treating a case, said the lecturer, two objects had to be kept in mind—namely, to cure the limp by providing a stable joint and to diminish the chances of arthritis. Both objects were best served by early reduction, preferably when the patient was between 18 months and 2 years of age. Permanent cure at this age, and even up to 5 years, meant, in the majority of cases, a practically normal hip. In older cases a cure could still be effected, though often without realizing the second object, the reduced hip being far from normal. During manipulative treatment, after apparent reduction, further leverage movements were necessary to get the head well home. There was a growing tendency in the United States, and to some extent in this country, to resort to open reduction as a routine. This procedure, though useful in old patients in whom the hips could not be reduced by manipulation, was, in Mr. Fairbank's view, to be condemned as a routine, on the grounds that it had no advantage over the simpler manipulative methods, by means of which, in the great majority of young patients, true reduction could be obtained. Ante-version was not a common cause of relapse, and its correction by osteotomy was rarely necessary. Failure of the upper lip of the socket to grow out was the cause of relapse.

Operative Procedures.

The advisability of attempting reduction after the age of 9 for a unilateral, and of 6 for a bilateral case, was very doubtful; the anatomical results were so bad that permanent benefit, even though reduction were obtained, was questionable. Hey Groves's method of transferring the head, enclosed in its capsular dome, to the acetabulum, which was gouged out to receive it, had no advantage over reduction coupled with a bone-grafting operation to make an upper lip. The making of an upper lip was a most useful operation when relapse was imminent after manipulative reduction, or when the latter, as in the case of a patient 4 years or older with a subluxated hip, held out little hope of cure. "Anterior transposition" by manipulation (*that is, transposing the head to the region* of the anterior inferior spine) when reduction was impossible, though difficult to achieve, was favoured by some surgeons. Adduction and flexion deformity were more satisfactorily corrected by osteotomy. Finally, the difficult problem of the irreducible adolescent or adult case suffering from pain and increasing disability had to be considered. Arthrodesis was the only operation which could afford permanent relief, and in unilateral cases it was the operation of choice. Osteotomy might be suitable for the adolescent with moderate pain and no æ-ray signs of arthritis, and it probably mattered little which method of osteotomy was used; opinions differed as to the value of this operation, and its mechanical and anatomical results called for careful consideration. The shelf operation—that is, the turning down of a bone flap or fixing a graft above the head, pulled down towards, but not to, the acetabulum—might increase the stability, but could not be expected to relieve arthritic pain for long. In a bilateral case it might be the only possible procedure when the other hip had been ankylosed. Mr. Fairbank condemned simple excision of the head. By this operation the pain, though at first relieved, soon returned, and the limp was much exaggerated.

ROYAL MEDICAL BENEVOLENT FUND.

SUBSCRIPTIONS are very urgently needed to enable the Committee to meet the many calls for financial help which are made by those members of the medical profession, their widows, and dependants who are afflicted by poverty and want, more especially at this time of year, when poverty is made the harder to bear owing to illness and bodily suffering. Every reader who is not already a regular subscriber is urged to consider whether one guinea at least could not be given in response to this appeal. Subscriptions and donations should be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, Cavendish Square, London, W.1.

At the last meeting of the Case Committee forty applications were considered and thirty-six grants were voted, amounting to £744 3s. The following is a summary of four cases.

Daughter, aged 46, of M.D. Left penniless on the death of her father, and, in spite of delicate health, trained as a nurse; she broke down badly after working at a hospital during the war. She attempted to resume work later, but in the end was forced to give up. She is now suffering from tuberculosis. There is no relation who can help. The Fund voted £36 towards the sanatorium fees, and with this as a start a friend who knows and admires this lady's uphill fight throughout her life is endeavouring to raise a special fund so that treatment in the sanatorium can be continued.

Daughter, aged 25, of L.R.C.P. Is suffering from tuberculosis and every hope is held out of a cure by immediate treatment. The applicant, however, has no private means to enable her to do this. Fund voted £25, and with the co-operation of the Guild enough money has been raised for one year's treatment.

Widow, aged 57, of M.R.C.S. Her husband died in 1929, having been a lunatic for the last years of his life. During these years his wife had had to attend her husband, and on his death such little income they had, amounting to £117 per annum, ceased. Her brother is able to contribute £26 per annum. Being an energetic and capable woman it is hoped that after she has had time to recover her health, which has been badly broken by all she has had to suffer, she will be able to find work and fend for herself. To give her the necessary rest and opportunity to find work the Fund voted £28 towards her maintenance.

Widow, aged 60, of M.B. Her husband died in November, 1928. After everything is settled and debts are paid the income which she may hope to receive from her husband's estate will be 15s. a week. Voted £30 in four instalments. Her total income will then be only £69 a year, but she hopes she may find some lodgers to take into her home and thus augment her income.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

NEW YEAR HONOURS.

THE list of New Year honours, which has been delayed owing to the illness of the King, was issued as a special Supplement to the *London Gazette* on March 1st. The names of the following members of the medical profession are included.

Baron.

Sir BERKELEY G. A. MOYNIHAN, Bart., K.C.M.G., C.B., M.S., LL.D., D.Sc., President of the Royal College of Surgeons of England, Consulting Surgeon to the Leeds General Infirmary.

Companion of Honour.

FLORENCE ELIZABETH, LADY BARRETT, C.B.E., M.D., M.S., B.Sc., Dean of the London School of Medicine for Women, President of the Medical Women's International Association.

K.B.E. (Civil).

CHARLES HUBERT BOND, C.B.E., D.Sc., M.D., F.R.C.P., LL.B., Commissioner, Board of Control.

D.B.E. (Civil).

Miss ANNE LOUISE MCILROY, O.B.E., M.D., D.Sc., Professor of Obstetrics and Gynaecology, Royal Free Hospital School of Medicine for Women, University of London; President, Maternity and Child Welfare Group of the Medical Officers of Health.

Knighthood.

KHAN BAHADUR NASARVANJI HORMASJI CHOKSY, C.I.E., *medical practitioner*, Bombay.

CARRICK HEY ROBERTSON, M.B., F.R.C.S., F.A.C.S.(Hon.), Surgeon to the Auckland Hospital, New Zealand.

C.B. (Civil).

Sir WALTER MORLEY FLETCHER, K.B.E., M.D., D.Sc., F.R.S., Secretary of the Medical Research Council.

C.M.G.

JOHN HOWARD LINDETT CUMPSTON, M.D., Director-General of Health and Director of Quarantine, Commonwealth of Australia.

FRANK COLE MADDEN, O.B.E., M.D., F.R.C.S., Dean of the Faculty of Medicine, Egyptian University, Cairo.

ARTHUR JOHN RUSHTON O'BRIEN, *M.C.*, M.B., Surgeon Specialist and in charge of the Gold Coast Hospital, Gold Coast.

AMBROSE THOMAS STANTON, M.D., Chief Medical Adviser to the Secretary of State for the Colonies.

C.I.E.

Lieut.-Colonel CHARLES ISHERWOOD BRIERLEY, I.M.S., Chief Medical Officer and Inspector-General of Jails, North-West Frontier Province.

Lieut.-Colonel ROBERT ERNEST WRIGHT, I.M.S., Professor of Ophthalmology, Medical College; Superintendent, Ophthalmic Hospital; and Medical Officer, Civil Orphan Asylums, Madras.

Lieut.-Colonel HAROLD HOLKAR BROOME, I.M.S., Principal and Professor of Surgery, King Edward Medical College, Lahore.

HENRY TRISTRAM HOLLAND, M.B., Ch.B., F.R.C.S.Ed., Medical Missionary, Baluchistan.

C.B.E. (Civil).

Miss MARY HANNAH FRANCES IVENS, M.B., M.S., Ch.M., Clinical Lecturer in Obstetrics and Gynaecology, University of Liverpool.

Lieut.-Colonel JOHN KENNETH SPROT FLEMING, O.B.E., Deputy Director-General, I.M.S.

O.B.E. (Civil).

NORMAN PARSONS JEWELL, *M.C.*, M.D., Resident Surgical Officer, European Hospital, Nairobi, Kenya.

JOHN CRICHTON STUART MCDOUALL, M.R.C.S., L.R.C.P., Director of Medical and Sanitary Services, Sierra Leone.

M.B.E. (Civil).

Miss ISABELLA HARDIE CURR, L.R.C.P., L.R.C.S., in charge of the McLeod Hospital for Women at Inuvil, near Jaffna, Island of Ceylon.

Kaisar-i-Hind Medal (First Class).

Mrs. PEARL SMITH CHUTE, Lady Doctor in charge of Canadian Baptist Mission Hospital, Akidu, West Godavari District, Madras.

JOHN HUTCHISON, L.R.C.P. and S.Ed., Church of Scotland Mission, Chamba State, Punjab.

NOWROJI JAMSHEDJI BANDORAWALA, Principal Medical Officer, Bikaner State.

Two other New Year Honours will be especially welcomed by members of the medical profession, with whom the recipients have long had very close association. Sir ARTHUR ROBERTS, K.C.B., Permanent Secretary, Ministry of Health, has been promoted to be G.C.B., and Miss WINIFRED CLARE CULLIS, O.B.E., M.A., D.Sc., Professor of Physiology, London (Royal Free Hospital) School of Medicine for Women, has been promoted to be C.B.E.

British Medical Journal.

SATURDAY, MARCH 9TH, 1929.

SECURITY OF TENURE IN PUBLIC POSTS.

A RECENT decision by Mr. Justice McCardie in the King's Bench Division, in the action *Brown v.* Dagenham Urban District Council, must have caused surprise and, indeed, consternation in the minds not only of members of the various public services, but of the average man, who has an idea that English law is the crystallization of common sense and of the universal desire for fair play. Throughout the long struggle for constitutional liberty in this country no right has been guarded more jealously than the fundamental principle that no man shall be condemned behind his back. Only a few weeks ago we had, in the Salvation Army case, an example of the importance the judicature attaches to the exact observance of this principle. The result of the Dagenham case seems to show that local authorities, in virtue of the extraordinary powers given to them by various Local Government Acts, may safely ignore this principle. The plaintiff in this action sought to recover damages, for alleged wrongful dismissal, from the urban district council, under whom he served as assistant overseer and clerk, and the case thus, incidentally, raised a question affecting the security of tenure of office for all local public officials, including medical members of the public health services. The question, his Lordship said in delivering judgement, was whether Section 189 of the Public Health Act, 1875, conferred on district councils a power of dismissal similar to that possessed by the Crown—a power of dismissal which could not be negatived or impaired by any contract of service. "The position created by the section is remarkable. I conclude that the council could dismiss its clerk, at pleasure, whatever might be the contract between them." The plaintiff's claim for wrongful dismissal, and his application for a declaration that he had not been dismissed from his office, therefore failed.

Complaint was made during the course of the action that the defendant council had given the plaintiff no opportunity of stating his case before they dismissed him from office. That, said his Lordship, was regrettable; but no right of hearing before dismissal was given by Section 5 of the Local Government Act. 1894, or by any other Act; and the plaintiff was not therefore entitled to a hearing. This is an amazing doctrine, but we suppose that we must take it as being law unless it is upset on appeal to a higher court. In these circumstances it seems to be beyond question that most officers appointed under the Public Health Acts can be dismissed at any time at the pleasure of the council under which they hold office, irrespective of any contract made between the council and the officer as to notice of termination of appointment. While Mr. Justice McCardie's decision in this case is based on Section 189 of the Public Health Act of 1875, it appears that similar powers are held by municipal corporations under the Municipal Corporations Act, 1882, and by county councils also, seeing that the provisions of the 1882 Act which relate to appointments and dismissals (Sections 17 and 19) are incorporated in the Local Government Act, 1888, which brought county councils into being.

County medical officers, and, indeed, most medical officers of health, have some protection owing to the fact that the consent of the Minister of Health has to be obtained before such appointments can be terminated by the local authority. But the fact remains that medical officers of health constitute only a small proportion of the whole number of medical officers in the local government service, and it seems clear that assistant medical officers in the public health service and in many public institutions can be dismissed at any time without reason at the pleasure of the council appointing them, and that any contract entered into between the local authority and the officer as to notice of termination of service is legally *ultra vires*. Clearly, the usual form of advertisement, which states that the appointment is terminable on either side by so much notice, is misleading, and future advertisements should indicate that the person appointed will hold office during the pleasure of the employing council. There is another aspect of this question which must add to the uneasiness with which officers in the public health service will have read of this action. If, as laid down by Mr. Justice McCardie, a local authority can determine an appointment at any time, the officers will lose all advantages of the Superannuation Act, except that they will be entitled to repayment of their contributions to the superannuation fund, with compound interest thereon.

It is, of course, true that incidents such as that disclosed in this action are rare, and we believe that few local authorities would act in the arbitrary way adopted by the Dagenham Urban District Council, but the possibility remains, and with it the feeling of uncertainty. It is therefore desirable that definite action should be taken by all interested bodies to effect a change which would bring the local authorities within the ordinary law which regulates the relations of employer and employed. And certainly it will be necessary to secure changes in the Local Government and Other Officers Superannuation Act so that an officer who has completed a certain number of years of service and is dismissed from his appointment shall be entitled, in the absence of evidence of misconduct, to a pension in accordance with his years of service, with due regard to Sections 9 and 11 of the Act.

The opinion expressed by Dr. H. C. McManus in two letters on this subject which have appeared lately in our columns, contending that most officers in the public health service and in other public medical posts are prejudiced by their lack of security of tenure, is materially fortified by the decision of Mr. Justice McCardie in the Dagenham case. From correspondence we have received it is apparent that many members in the public services are looking to the British Medical Association to do all in its power to improve their present position as regards security of tenure, to counter so far as possible the effects of Mr. Justice McCardie's recent judgement, and also to deal with the points we have just raised in respect of superannuation. The matter is coming before the Public Health Committee at its meeting this week, and we have no doubt that the Council of the Association, on the advice of that committee, will seek the co-operation of other interested bodies in pressing on the attention of the Minister of Health and of Parliament the necessity for prompt action which will clear up the most unsatisfactory situation now disclosed, and will give to members of the public services a sense of security so long as they carry out their duties in a satisfactory manner.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

IT is doubtful if the importance of midwifery and gynaecology in the medical curriculum is even yet fully recognized by the general body of professional opinion. The tendency rather is to regard the study of medicine and surgery as fundamentally important, and somewhat indiscriminately to class all other branches of practice—for example, orthopaedics, ophthalmology, oto-rhinology, midwifery, and gynaecology—under the heading of specialties. With the growing complexity of medical studies it is inevitable, perhaps even desirable, that certain subjects and groups of subjects should shift from the province of the general practitioner to that of the professed expert. Few would deny, for example, that this holds good in the case of ophthalmology. Can it be maintained that it is true of obstetrics and gynaecology? These two together form a single well-defined whole, whose position to-day as one of the three subjects of a qualifying examination can be traced back to the Medical Act of 1886—"A qualifying examination shall be an examination in medicine, surgery, and midwifery."

It may be questioned, furthermore, whether in any branch of practice so much depends on the knowledge and skill of the ordinary general practitioner as in the practice of midwifery. The general practitioner, as a rule, does not conduct major surgical operations; whenever possible he calls in a surgeon, or sends his patient to a hospital. Even medical cases, if they present exceptional difficulty, may often be dealt with in a similar manner; a consultant may be called in, or the patient may be transferred to a general hospital. But most of his midwifery the general practitioner has to conduct himself; if an emergency arises he must be adequate to meet it; the shortage of maternity beds is general throughout the country, and only rarely at present is he in a position to call in the aid of a specialist. When the fact is added that 3 000 women die each year as the result of childbirth, and that 75 per cent. of the diseases of women owe their origin to what should be a physiological act, it must surely be admitted that every movement to improve the undergraduate and post-graduate teaching of midwifery and gynaecology merits the closest and most sympathetic attention. Such a movement is that initiated by a number of the leading teachers, past and present, of these conjoined subjects in the United Kingdom, to form a British College of Obstetricians and Gynaecologists, with the object of encouraging the study and improving the practice of obstetrics and gynaecology.

The proposed College, of which provisional Articles of Association have recently been drawn up, aims at establishing a Fellowship and admitting to such status those medical practitioners judged by the College to have advanced the science and art of obstetrics and gynaecology. The difficulties involved in constituting the foundation Fellowship and foundation Membership are to be met by making only practitioners engaged in teaching students and graduates at approved hospitals eligible for nomination to the Fellowship, and those holding staff appointments in approved non-teaching hospitals eligible for nomination to the Membership. The promoters further propose to admit to honorary Fellowship of the College not only distinguished obstetricians and gynaecologists, but other eminent persons, whether members of the medical profession or not. Among the objects of the proposed College is the institution of a post-graduate diploma in obstetrics and gynaecology, and authority is being sought to co-operate at some future time, if invited, with existing licensing bodies in the examination of candidates for qualifying diplomas. The post-graduate diploma would be granted only to registered medical practitioners. The College hopes to foster the study and improve the practice of obstetrics and gynaecology by advising in regard to technical training, instituting lectures and demonstrations, and diffusing information on all matters relating to this branch of practice by means of periodicals, books, or other publications. Among its wider activities the College contemplates the possibility of promoting or opposing any legislative or other measures affecting the practice of obstetrics and Gynaecology. In the draft Articles of Association it is laid down that the council shall consist of twelve Fellows and six Members, elected territorially, together with a president, treasurer, and honorary secretary, each of whom must also be a Fellow or Member of the College.

The Memorandum and Articles of Association will be signed by Dr. Henry Russell Andrews, Professor William Blair Bell, Mr. Comyns Berkeley, Sir Francis Champneys, Bt., Dr. Thomas Watts Eden, Professor John Martin Munro Kerr, Professor Charles Gibson Lowry, Sir Ewen John Maclean, and Professor William Fletcher Shaw, and we understand that the project has the approval of every professor of obstetrics and gynaecology in the United Kingdom. The College is thus well sponsored, and its objects will, we think, commend themselves to all who have at heart the progress of obstetrics and gynaecology.

THE HONOURS LIST.

To the medical profession there are two features of more than ordinary interest in the list of New Year Honours which was published on March 1st after a delay of two months owing to the illness of the King. One is the barony conferred on the President of the Royal College of Surgeons of England, and the other is the recognition accorded to a number of women engaged in the work of medical education.

Sir Berkeley Moynihan's elevation to the peerage will be widely welcomed, not only on personal grounds but because it is the first time this honour has been paid to a surgeon in the active practice of his profession. There has been a growing tendency of late years to add to the House of Lords men engaged in the varied intellectual activities which make up the life of the nation; and it is good that the Upper House of the Legislature should have the advantage of the counsel of another practising member of our profession who has identified himself with the forward movement in science, practice, and organization. His knowledge of public and professional affairs and his gift of clear exposition should prove of great value when matters affecting the health of the community are before Parliament. There is no need for us to dwell on the services Sir Berkeley Moynihan has rendered to the science and art of surgery, or on the reputation he has won for himself as operating surgeon, teacher, and orator; his name is a household word, not only in this country, but throughout the medical profession in every part of the world.

Lady Barrett, Dean of the London School of Medicine for Women, is the first medical woman and the third member of our profession to be awarded the high distinction of admission to the Order of Companions of Honour. Her colleague Dr. Louise McIlroy, Professor of Obstetrics and Gynaecology, becomes Dame Commander in the Order of the Bri[illegible]

Empire; and another member of the teaching staff of the London School of Medicine for Women, Dr. Winifred Cullis, Professor of Physiology, is appointed a Commander in the same Order. Miss Frances Ivens, Clinical Lecturer in Obstetrics and Gynaecology in the University of Liverpool, is also awarded the C.B.E. Another distinction which will give particular pleasure to the medical profession is the K.B.E. conferred upon Dr. C. Hubert Bond, Commissioner of the Board of Control, whose work for psychological medicine and for the mentally afflicted is well known to our readers.

LORD DAWSON AND THE LOCAL GOVERNMENT BILL.

THE main feature of the debate on the second reading of the Local Government Bill in the House of Lords was a speech by Lord Dawson of Penn. For this pronouncement he deserves well of the medical profession and the public. Lord Dawson, while favourable to the bill in general, confined his observations to those provisions which dealt with the reform of public health administration, and pointed out two dangers which were inherent in the bill as it stood, but against which it would, if the Government were willing, be quite easy to provide safeguards. These dangers are two of those to which the British Medical Association has prominently drawn attention, and which have been more than once commented upon in articles in the *Journal*. New public health duties will, under the proposals of the bill, be placed upon the councils of counties and of county boroughs, and many of these duties, more particularly in the case of counties, are different in kind from any that the councils have previously been entrusted with. The establishment and management of hospitals for the treatment of general medical and surgical conditions is one of these duties, and though some of the councils have some experience with regard to hospitals for notifiable infectious diseases, to tuberculosis sanatoriums, and, to a smaller extent, with regard to maternity homes, this cannot be held to equip either the councils themselves or their medical officers of health adequately or fully for their new duties. It will, too, be possible for the councils to conduct their hospitals, whether transferred from the Poor Law guardians or newly established, either in competition with, or in co-operative organic connexion with, any existing voluntary hospitals, large or small, in their area. Lord Dawson, voicing the emphatic opinion of the medical profession as well as his own, stated that the latter method was the only reasonable one, and that in any case it would be foolish to "start a new venture, and a sound venture, which might lead to a wide establishment of municipal hospitals for curative medicine in this country and neglect all the traditions and the knowledge that had been gained during the years" by those, both medical and lay, who had been intimately associated with the work of the large voluntary hospitals. Lord Dawson therefore pleaded that the power to co-opt such experienced persons on the committee of the council entrusted with the establishment or conduct of hospitals should be converted into a duty, and so be secured instead of being merely a possibility. He referred to the committee in question as the Public Assistance Committee; but though this is indicated in the bill, perhaps with undue emphasis, as a possible arrangement, councils are not bound to adopt it in their administrative schemes. It is to be hoped that councils will in those schemes—at all events in the case of all county boroughs and many counties—assign their hospital functions to their Public Health Committees, which may, under the bill, equally contain a minority of co-optative members. Even if, in the case of some counties, it may prove a more convenient immediate arrangement to leave transferred hospitals under the Public Assistance Committee, this should be merely a device for gaining time, and they should, after a defined and limited period, pass under the control of the Public Health Committee, possibly by means of a hospital subcommittee of that committee. In any arrangement, should co-option remain permissive only, every effort ought to be made to secure it. Lord Dawson's second main point was connected with his anxiety—shared by the British Medical Association—lest the general body of private practitioners should be dissociated from the health work of the local authorities. He observed that "up to now the medical staff of the health services of this country had been run by a small number of medical men. They had been men who had specialized in preventive medicine—medical officers of health, tuberculosis officers, school medical officers. Ever since the Ministry of Health Act was passed it had been a regrettable fact that the policy of these official doctors proceeded on lines totally divergent from those doctors who constituted four-fifths of the profession and who belonged to the curative branch. That divergence was lamentable." There is some over-emphasis here, but Lord Dawson's suggestion was that in each area "there should be set up, under the chairmanship of the medical officer of health, an advisory council of doctors." Such a representative advisory statutory medical council has been proposed by the Association, but it is not at the moment being pressed for. The opinion is that in present circumstances the very important end desired may be better attained by securing co-option of members of the general profession on the various committees of councils dealing with the public health services, and by bringing about a closer connexion between Divisions or Branches of the Association and the councils and chief medical officers of local government authorities. If this can be achieved there may be developed a real alliance between prevention and cure in health matters, for both are the concern of, and, in fact, are largely practised by, public health medical officers and private practitioners alike.

EVOLUTION OF THE HUMAN FOOT.

THE H. O. Thomas Memorial Lecture, which was delivered by Sir Arthur Keith at Liverpool last May, has now been published in the *Journal of Bone and Joint Surgery*; it will repay careful study. Like all Sir Arthur Keith's handiwork, it is characterized by learning, research, keen observation, and clarity of exposition. He returns to an aspect of the subject with which he dealt nearly seven years ago (*British Medical Journal*, 1922, i, 736), filling in detail and adding the results of new investigations into the evolutionary history of the human foot. Taking as examples the feet of pronograde monkeys, orthograde apes, and man, this fascinating inquiry leads us to a study of the anatomy of the foot in each of the genera considered, and of the evolution of the muscles and tendons, in response, as it were, to the calls made upon them by the needs and habits of each genus or species. The importance of muscular action in the maintenance of an efficient foot has been long insisted upon by Sir Robert Jones, and the anatomical and developmental evidence brought forward by Sir Arthur Keith fully supports this view. The fate of ligaments when unsupported by muscles can be seen by all who will look at the deformities following anterior poliomyelitis, while, on the other hand, the apparently flat foot of the stage dancer shows that well-developed muscles can render the foot highly efficient, notwithstanding great laxity of ligaments. The mechanical arch of the foot, in an architectural sense, with its so-called keystone, is a figment of the imagination, and belief in its existence can only be retained by those whose mechanical insight is as small as their appreciation of the role of muscles. In examining the form and functions of the foot it is necessary, as Sir Arthur Keith points out, to bear in mind the

important consideration that evolutionary alterations in the human foot involve widespread changes in all the systems of the body, and that the type of foot of the orang, the gorilla, the chimpanzee, the gibbon, and others is the response of evolution to the demands of the whole organism. Lord Monboddo, with his admirer Peacock, and others, believed that modern man was the degenerate descendant of giant ancestors. In a sense Sir Arthur Keith supports this view, for he sees reason to think that we may be descended from giant arboreal ancestors, whose bodies, like that of the East African gorilla, became too heavy for climbing; they adopted, therefore, a terrestrial life, and developed a heel-bearing *plantigrade foot*. This study of the structure, and especially of the muscles of the foot of the gibbon, the great apes, and man, shows beautifully how the human foot may have developed from that of an unknown arboreal ancestor to its present state; Sir Arthur Keith confesses his ignorance how this has been brought about, but declares his certainty that the change has been effected "by biological means which are still resident in the body and will be discovered." The forces which we call Providence or Nature have thus, through uncounted ages, been busy fitting us with feet suited to the needs of barefooted man, but European man compresses all this elaborate mechanism of bones, muscles, and ligaments into a stiff unyielding case, which allows only a few of the crudest movements of the foot. We may judge to what an extent this restriction has been carried by the fact that the movements of the foot in everyday use can be so successfully imitated by an artificial one as to defy detection when the amputation is below the knee. Yet such a prosthesis, in place of the elaborate mechanism of the living foot, has only one joint which allows a hinge movement at the toes, and another outside the foot proper, at the ankle. Woman, meanwhile, emulous of her pronograde ancestor, raises her heel three inches from the ground, and destroys the efficacy of the hallucial lever by forcibly squeezing her great toe into a position of complete mechanical inefficiency. Yet despite this her athletic achievements surpass all that we have heard of Atalanta or the Amazons.

RADIUM FOR THE LONDON HOSPITALS.

To a distinguished gathering, which included the Lord Chancellor (Viscount Hailsham), at a reception at the Wellcome Historical Medical Museum on March 1st, Sir John Rose Bradford, P.R.C.P., explained the methods which the committee of the King Edward's Hospital Fund proposes to adopt in utilizing the radium purchased with Sir Otto Beit's gift of £50,000. It was much regretted that Sir Otto Beit himself was prevented by illness from attending. Sir John Rose Bradford reminded the company that this generous gift was not the only service that Sir Otto Beit had rendered to medicine; many years ago he gave a large sum to be expended in the foundation of fellowships for the pursuit of investigations into the causes and nature of disease. The problem of dealing, on behalf of the London voluntary hospitals, with a gift of £50,000 for the purchase of radium, Sir John Rose Bradford said, had not been an easy one. The quantities of radium at present available, owned or on loan, at the hospitals had first to be ascertained. No one hospital possessed quantities approaching those available at some treatment centres on the Continent, nor would possess such quantities even as a result of this gift and of the gifts of £25,000 to the London Hospital for the same purpose. The decision of the Fund committee was that, in the first place, a certain very limited number of hospitals should be provided with a quantity of radium sufficient to enable them, with their own supplies, to function as radium centres, not only treating their own patients, but supplying radium emanation to other hospitals; and, in the second place, that there should be distributed among the hospitals in a more general way, as far as the amount at the disposal of the Fund permitted, such supplies as would enable them to treat, if not all, a certain number of their patients who required radium treatment. Certain special hospitals—those dealing with diseases of women, for example—had greater immediate need of radium than others. Three of the twelve large teaching hospitals had, or would shortly have, as a result of specific donations, quantities of radium of their own sufficient to provide radium emanation, and at present would not share in the Beit allocation. In another case an allocation would be made sufficient in amount, with the radium available at the hospital, to provide emanation. Thus four radium centres would be established. Some of the other teaching hospitals had only very small quantities in their possession, and one of them had none at all. After allocation through the Fund these would all have quantities adequate to meet at least some of their needs. Allocations would also be made to certain of the general hospitals without schools, to the hospitals for diseases of women, and to some of the other special hospitals, having in view the nature of the diseases treated by them. These hospitals had been asked to inform the Fund of the measures they proposed to take for the use and custody of the radium. Sir John Rose Bradford instanced the chief regulations which had been made for the distribution. The radium would be on loan to the individual hospital for one year, and would be subject thereafter to withdrawal at one month's notice. It would be available for all hospital patients, ordinary or pay-bed, but it was not to be removed from the hospital premises without the written authority of the Fund. Periodical reports from the hospitals would be expected, showing the stocks of radium, the milligram hours of use, and the number of patients treated. In conclusion, Sir John Rose Bradford emphasized the urgent demand for larger amounts of radium, especially for research into the best methods of treatment. He also mentioned that approximately one-quarter of the fund available had to be expended on the costly provision of containers and the placing of the radium therein. Before the gathering broke up a vote of thanks was accorded to Mr. Henry S. Wellcome for his hospitality, and Mr. Wellcome, after describing the radium benefaction as one of the finest pieces of Samaritan service to the community, spoke of his expectations with regard to the future of his museum, which, he said, was as yet in its infancy, and occupied merely a temporary abiding place. It was his hope to rehouse the entire collection. The exhibits represented, he said, only one-tenth of those available.

UNIVERSITY HYGIENE.

HYGIENE, as understood in this country, has a wider and a narrower meaning. In its wider sense it is the rule of health for the whole community. In its narrower sense it is a special system or way of living enjoined upon people who can be grouped together as sharing common risks or a common environment peculiar to their group. In this narrow sense we speak of naval or military hygiene, of school hygiene, or industrial hygiene, as special departments in each of which the distinctive factor is readily apparent, but we do not speak in the same definite way of university hygiene, since no specific code of health for undergraduates has so far been laid down. The country doubtless is not indifferent to the welfare of the members of its universities, but their general circumstances and occupational conditions have not hitherto been thought to mark them out as a class in need of organized health guidance. In North America such guidance is in many cases freely given, and university hygiene there often represents an extensive field of activity. It may embrace the medical inspection of freshmen and

follow-up inspections in later years, the supervision of gymnastic training, the discovery and employment of athletic talent, the care of the sick undergraduate and his medical or surgical treatment in hospital. In these particulars, as is pointed out by Dr. Robert Jacquet, president of the National Students' Union of France, in his essay on university hygiene,[1] America is ahead of England and France; but whereas in England the average undergraduate, a member of a "caste sportive et fortunée," may stand little in need of organized health care, the French student too often is under hygienic and other disabilities for which some remedy is urgently required. The lodgings available to students in France are usually of an inferior type, dark, ill ventilated, and inadequately heated, and the standard of attendance may not be high. The hostels provided by the universities themselves are an improvement on these furnished lodgings, but are frequently situated in some old quarter of a town, with narrow streets and a thronging population. At Nancy, however, a residential college is being built in a fine open park round the château of Montbois. Sport in the French universities appears to have fallen from its high ideals of twenty years ago. It no longer seeks to foster manliness. It has become, instead, a commercial enterprise, in which the search for champions has been carried to inordinate lengths. University sport, in Dr. Jacquet's view, should be taken from the hands of trainers, and committed, in its medical and ethical aspects, to the general charge of the Minister of Education, the governing body of each university assuming the responsibility of local management and arranging time tables so as to give each undergraduate free access to the playing fields. In the matter of feeding all but two French universities have restaurants of their own. These places are under student management, but with the best will in the world, Dr. Jacquet thinks, the student manager has neither the time nor the training to make himself a competent restaurateur. The town councils of university towns should assume this charge, by way of return for the distinction and profit they derive from the presence of a university in their midst. Hygiene should be taught to all undergraduates, not students of medicine only. Any vocational examination of boys to ascertain their fitness for a profession should be carried out by medical men, aided, it may be, but certainly not displaced, by physiologists or psychologists. Approval is expressed of university dispensaries, convalescent homes, rest camps, and accommodation for open-air teaching. Dr. Jacquet's essay is an earnest appeal on behalf of the student community of his country, and its effects are sure to be watched with sympathy on this side of the Channel.

VARIETY IN REPETITIVE WORK.

THE latest report[2] issued by the Industrial Fatigue Research Board deals with a matter which, in one form or another, must have engaged the attention of every intelligent worker in any sphere—a comparison of the effects produced by variation and by uniformity in work. An earlier investigation showed that in most repetitive processes in industry the operations are not repeated with mechanical precision, but that some variety is introduced, either by a cessation of work or by some change in its nature. This arises sometimes from the conditions of the work and sometimes from the action of the operator. Subsequent inquiry has yielded inconclusive evidence as to the effects of variety upon output, and Mr. Wyatt and his colleagues accordingly attempted first to clear the ground by investigating the result of introducing changes into certain repetitive processes—soap wrapping, handkerchief folding, and bicycle chain making—and then extended their inquiry to three other processes—tobacco weighing, cigarette making, and assembling cartridge cases—in an effort to determine (1) the optimum duration of one form of activity before changing to another, and (2) the most suitable type of work for the alternating processes. They found that when the form of work was changed at specified times within the work spell, output was usually increased, and a steadier rate of working was maintained. Results were most favourable where there was a substantial difference in the successive tasks performed, but although output was not much affected in such cases minor changes in the nature of the work done were welcomed by the operatives. Where numerous changes were made the results were unsatisfactory; the "swing of work" was interrupted, and the maximum rate was seldom attained. The most suitable interval between changes in the form of activity proved to be from one and a half to two hours; and output was higher when changes were made at prearranged times than when made casually at the whim of the operatives. This brief summary of the investigators' conclusions does not do full justice to their work, for their inquiry, like others of this series, opens up several new avenues of investigation and brings to light facts which should prove of considerable value to those engaged in industrial administration. The report is not explicitly of much medical interest, for it is concerned mainly with the relation between output and certain aspects of working conditions in the factory, and does not deal directly with the psychological or physiological sides of the question. It gives, however, some interesting notes on the mental attitude of the operatives concerned in the experiments. Such documents, moreover, should be of some value to those engaged in general practice in industrial areas. Lastly, there is a strong "human interest" in investigations of this nature. Which of us, having performed any long and tedious task, can fail to sympathize with the girl operatives employed in fixing lids to cigarette tins who, having been supplied with lids in batches of three gross at a time during the investigation, objected at its conclusion to reverting to batches of five gross? The change made no difference to the amount of work to be done, but, as the report observes: "A certain amount of pleasurable satisfaction is evoked by the successful completion of a task, even though it is only part of a larger whole."

INCIDENCE OF TUBERCULOSIS IN ADELAIDE.

IN the course of his report on the state of the public health of the city of Adelaide for the year ending September 30th, 1928, the medical officer of health, Dr. E. A. Johnson, gives an account of an interesting investigation into the prevalence of tuberculosis among hospital patients. Dr. J. B. Cleland, professor of pathology in the University of Adelaide, made an analysis of his findings in 800 unselected cases on which he had personally conducted *post-mortem* examinations. Many of these cases came from the public hospitals, some even from the consumptive home, so that the incidence of tuberculosis found in this investigation was probably higher than among the general body of the population. Yet of the 800 cases under consideration as many as 527 were shown by necropsy to be free from any tuberculous focus. The 273 to be accounted for included 230 with definite tuberculous lesions; in 103 of these the lesions were healed and calcified; in 11 the lesions were small and healing or quiescent, and only in 51 were there extensive pulmonary lesions. In 43 cases slight lesions were present, but the evidence as to their possible tuberculous nature was indefinite. In short, among 800 hospital

[2] Report No. 52. By S. Wyatt, M.Sc., M.Ed., and J. A. Fraser, M.A., B.Ed. (assisted by F. G. L. Stock). *London:* H.M. Stationery Office, or through any bookseller. 1s. 3d. net.

patients approximately 550 had no obvious tuberculous lesions, while in a majority of the rest what lesions were present were slight, quiescent, or healed. The figures are interesting in view of the far greater prevalence of pulmonary lesions one would expect to find in the course of a similar investigation among hospital patients from a large European centre.

INFLUENZA.

As pointed out in our note of last week (such a note necessarily goes to press before the returns of the current week are available) the course of the mortality ascribed to *influenza* and of the notified prevalence of pneumonia down to the week ending February 16th suggested that the maximum for the whole country had been reached, although increases were still taking place in the Midlands, the North, and Yorkshire. The returns for the week ending February 23rd showed, however, that this expectation was not fulfilled. In London itself, although the notifications of pneumonia continued to decline—the returns for the three weeks ending with that of February 23rd were 689, 562, and 554—the deaths ascribed to influenza increased from 393 to 473. The expected increases in the Midlands, the North, and Yorkshire were larger than had seemed probable, so that the total of notifications of pneumonia, which had fallen in the week ending February 16th to 3,658 (3,898 in the previous week), increased sharply to 4,451. There has been a corresponding but patchy increase in the numbers of deaths from influenza in the great towns, so that the total mortality, 1,764, was very large—40 or 50 per cent. greater than might have been anticipated. One naturally asks whether the unfavourable turn can be attributed to weather conditions. The returns of the week ending February 16th showed no sign of this, but in those of the week ending February 23rd there is a decided increase in the proportion of deaths from influenza at ages over 65, so that this proportion, already large, had become the greatest yet recorded this year. In 1895, a year also blessed—or cursed—with prolonged cold in February, there was also a sharp increase of mortality ascribed to influenza and respiratory diseases—indeed, a sharper increase than this year. Hence the weather may be given the credit of part of the unfavourable turn taken by the prevalence of influenza. In the circumstances it would be even rasher than it usually is to prophesy when the wave of mortality will subside. Clinically the type of illness continues to be generally mild, but we cannot doubt that the winter of 1928-29 will prove to have been an unfavourable one for those in the decline of life.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE nineteenth annual meeting of the Oxford Ophthalmological Congress will be held on July 4th, 5th, and 6th, 1929, under the presidency of Mr. A. B. Cridland. The members will assemble at Keble College (where accommodation has again been offered) on the evening of Wednesday, July 3rd, and on the following morning there will be a discussion on "Diseases of the lacrymal apparatus," introduced from the ophthalmological aspect by Professor Joseph Meller of Vienna, and from the rhinological by Dr. J. S. Fraser, surgeon to the ear, nose, and throat department, Edinburgh Royal Infirmary. The Doyne Memorial Lecture will be delivered on the morning of July 5th by Dr. Ida Mann, her subject being "Some observations on the vascularization of the vertebrate eye." On Friday afternoon there will be a discussion on the "Ocular manifestations found in fractures of the skull," to be opened from the point of view of the general surgeon by Mr. Hugh Cairns, and from that of the ophthalmic surgeon by Mr. Charles Goulden. Miscellaneous papers and demonstrations are also being arranged, and one afternoon will be given up wholly to demonstrations. The annual dinner of the congress will be held on July 4th in the Hall of Keble College. The full programme will be issued in June. All communications should be addressed to Mr. C. G. Russ Wood (12, St. John's Hill, Shrewsbury), who is acting as honorary secretary.

ROYAL COLLEGE OF SURGEONS COUNCIL ELECTION.

THE Secretary of the Royal College of Surgeons of England has sent out the usual election notice, which on this occasion informs the Fellows of the College that on Thursday, July 4th, at 11 a.m., there will take place an election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir H. J. Waring, Mr. C. H. Fagge, and Mr. W. Sampson Handley, and by the resignation of Sir James Berry. Blank forms of nomination and of the requisite notice from a candidate may be obtained on application to the Secretary, and the same must be received by him, duly filled up, not later than Monday, March 18th. A voting paper will be sent by post on April 2nd to each Fellow whose address is registered at the College. The candidate elected by the smallest number of votes will become substitute member of Council for Sir James Berry until 1931.

THE annual Harveian Lecture before the Harveian Society of London will be given by Dr. E. Graham Little, M.P., on Thursday next, March 14th, at the Paddington Town Hall, Paddington Green, at 8.30 p.m. The subject of the lecture is "The medical profession, the voluntary hospitals, and the De-rating Bill." As this measure is of great importance to the whole medical profession, all practitioners and students are cordially invited to attend.

UNDER the auspices of the National Council for Mental Hygiene, Sir Maurice Craig, M.D., will deliver a lecture on the problem of nervous breakdown, at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Wednesday, March 13th, at 5 p.m.

WE regret to announce the death of Alex Hill, M.D., F.R.C.S., who was in succession Master of Downing College, Cambridge, Principal of University College, Southampton, and secretary of the Universities Bureau of the British Empire.

THE KING.

THE bulletin issued from Craigweil House, Bognor, on Saturday, March 2nd, after an interval of a fortnight, laid stress upon two points. One is that the King continues to make slow but steady progress. The other is that the complete recovery which is confidently looked for must not be endangered by premature exertion of any kind. "One of the most anxious features of His Majesty's grave illness was severe exhaustion due to prolonged toxaemia. For this reason careful avoidance of any sustained effort of body or mind will be necessary for a lengthened period." The logic of this will be apparent to every medical reader who recalls the violence of the streptococcal infection, the length of the acute stage of the illness, and the prostration which follows such bad infections even in young patients. For weeks on end the King's life hung in the balance, and restoration to health after so severe and so protracted an illness must be a matter of months.

INDUSTRIAL MALADIES.

LECTURES BY SIR THOMAS LEGGE.

SIR THOMAS MORISON LEGGE, C.B.E., M.D., late Senior Medical Inspector of Factories, has delivered on the last three Monday evenings the Shaw Lectures of the session to the Royal Society of Arts, his general subject being "Thirty years' experience of industrial maladies." In his first lecture, however, Sir Thomas Legge explored a more pleasant territory, telling his audience how in his rounds of factory inspection he had kept a disengaged eye for the "looks" of the worker, and had divided female workers into categories of beauty. Thus he had found some factory girls—and he showed photographs to prove it—whose features recalled the work of Rossetti and Burne-Jones and the Greek type generally; others recalled Reynolds, Gainsborough, Raeburn, and Lawrence, and others again, of the more "pretty" type, were after *Romney. These, of course, were young women, under* 30; the marks of age appear quickly on the factory worker, and had he taken the age period 31 to 40, instead of 18 to 30, he would have found, not 72 per cent. of good looks, as with the younger women, but only 25 per cent. One great improvement in looks as also in health was due to the disappearance of the anaemia which he was accustomed to find thirty years ago among the young women employed in factories. He also noticed the splendid teeth of women workers in the East End of London, in striking contrast to their sisters in the North of England.

Prevention of Occupational Diseases.

In his second lecture, speaking of the prevention of occupational diseases and poisonings, Sir Thomas Legge said that he had come to certain conclusions which he could express as aphorisms. He enunciated them bluntly in a *wholly impartial spirit*, having the greatest respect and regard for both sides in industry, employers and employed: "Unless and until the employer has done everything, the workman can do next to nothing to protect himself." "If you can bring an influence to bear external to the workman—that is, one over which he can exercise no control—you will be successful, and if you cannot or do not, you will not." "All industrial lead poisoning is due to the inhalation of dust and fumes, and if you can stop their inhalation you will stop the poisoning. It is not due to dirty hands—that is, eating with unwashed hands." He proceeded to give some examples of how influences external to the workman had resulted in great improvement, if not in the disappearance of the malady, after mere regulations had proved a failure. One of these was, in match manufacture, the substitution of sequi-sulphide of phosphorus for yellow phosphorus; another the conversion of *pulp white* lead into oil paint ready for the market in automatic closed-in machines, so successfully achieved by the white-lead makers; yet another the use of low solubility glaze in pottery manufacture. Commenting upon the great diminution in the number of cases of lead poisoning since 1910, Sir Thomas Legge said that this was due in a measure to the fact that employers began to appreciate the risk of using lead and to the improved appliances for removing fumes and dust. Strict regulations by the Home Office had accounted to some extent for the remarkable fall in the number of cases occurring in the white lead industry, but ten times as important in this respect had been a discovery made within the trade itself. It was found that white lead would mix more readily with oil than it would with water, and that if white lead were put in a closed machine with oil the two would mix together intimately, and would come out at the other end as lead ready mixed for the painter. This was an important achievement, and had had a far-reaching influence in reducing the number of lead poisoning cases.

As for the pottery industry, if he were asked what was the sheet anchor for the protection of a worker in the dangerous trades, he would say the provision of fans for carrying away dust, but here again what had given the *coup de grâce* to lead poisoning in the pottery industry had been a revolution in technique, brought about this time by an invention by Sir Edward Thorpe, then Government chemist, who discovered that if the glaze and lead used in pottery were mixed in definite proportions with a certain amount of ground siliceous material it would form a bi-silicate of lead which was insoluble in the alimentary canal and also in the lungs. Thus it came about that low solubility glaze was used in the pottery industry to-day. An industry in which lead poisoning had appeared since the war was ship-breaking. The armour plating of battleships was cut up with an oxy-acetylene pipe, and when the flame came into contact with the red lead paste at the back of the plates it volatilized the lead and created a fume which was inhaled by the workman and caused illness. There had been an extraordinary rise in the number of cases due to the inhalation of this fume, and this indicated once more that lead poisoning was due to the inhalation of fume or dust, and not to swallowing, because in this particular instance there was nothing that could be swallowed. Here, again, it seemed necessary to emphasize that to stop lead poisoning it was important to get some means external to the workman over which he could not exercise control, and not to rely upon wash-basins, respirators, or gloves, because the lead that caused the trouble did not go through the skin.

In the accumulator industry the most dangerous processes were concerned with what was called the pasting of the plates. If only some means external to the worker were found whereby the plate paster could be made automatic there would be an immediate drop by about 50 per cent. in the number of cases of lead poisoning in the accumulator industry. Short of this, however, a great deal could be done, and indeed had been done, in the accumulator industry to mitigate the risks which the workers ran in inhaling lead compounds. In one particular accumulator factory, among about 1,000 persons exposed to lead, there were 11 cases of lead poisoning in 1926 and 18 cases in 1927. The firm in question recognized the necessity for tackling the problem, and carried out improvements to a very high state of perfection. The first thing done was to appoint a whole-time medical officer, who immediately began to study the processes and the risks attending them, examining also the effect upon the blood of the workers. As a result of the measures taken not a single case of lead poisoning occurred in that factory last year.

Diseases Scheduled for Compensation.

In his final lecture, Sir Thomas Legge spoke from twenty years' experience of compensation for industrial diseases. After dealing with several of the diseases and forms of poisoning scheduled, he said that he thought the time had come to consider whether chronic poisoning by sulphuretted hydrogen gas should not be added to the list of scheduled diseases. If this were done he had no doubt that it would stimulate, before long, the discovery of some means external to the workman, such as locally applied exhaust ventilation, which would cause the disease to become a negligible factor. No one knew what new occupational maladies, involving an enlargement of the schedule, might arise as a consequence of industrial developments in chemistry. Poisoning from tetrachloride or from manganese was undreamed of when workmen's compensation was instituted. One disease, asbestosis, he thought, would have to be scheduled in the same way as silicosis, which in its symptoms it resembled.

Sir Thomas Legge (whose chairman was Mr. Ben Tillett, a well-known trade union secretary) devoted a large part of his lecture to explaining some of the useful suggestions with regard to previously disregarded maladies that had been brought forward by trade union secretaries. One such secretary, himself almost blind, was the first to direct attention to glassworkers' cataract. As a consequence, Sir Thomas Legge went down to St. Helens and examined the eyes of 500 glassworkers who had been subjected to the glare of the furnace, taking 278 other persons, not so exposed, as controls. He found among the 500 glassworkers that in the right eyes of 64 and the left eyes of 72 there were quite obvious changes, whereas among the controls the figures were 14 and 13 respectively. The reason why among glassworkers the left eye was more often affected than the right was because the left eye was turned inwards upon the "glory hole" of the furnace. After these and other investigations on the frequency of senile cataract, he had

no hesitation in concluding that glassworkers were specially subject to the condition, and recommending the scheduling of the disease. The same trouble was subsequently discovered among men exposed to the glare of molten iron.

Another instance in which the suggestion of a trade union secretary had been of value was with regard to a form of poisoning brought about among shuttle workers when West African boxwood (*Gonioma kamassi*) was used. Such workers were noticed to show a tendency to doze, almost falling from their benches, and it was discovered that the wood contained an alkaloid which was a very powerful depressant of the heart. He examined numbers of men suffering from that form of poisoning, with the result that the condition was scheduled; but the use of the wood had now been discontinued, other woods taking its place, and there had been no more cases.

It was another trade union secretary who noticed how the makers of briquettes or patent fuel suffered from the effect of the pitch which constituted 10 per cent. of the briquette. The lecturer had examined a large number of men, and found the frequent occurrence of skin cancer from this cause. In the years 1920–26, amongst patent fuel workers there were 143 cases of epitheliomatous ulceration or skin cancer for which compensation was paid, and the number of deaths was only 5; but in other trades the proportion of deaths to notified cases was much larger. For example, in tar distilleries there were 89 cases and 12 deaths; among the retort men employed at gasworks, 41 cases and 16 deaths; and among mule-spinners (no doubt whatever due to a mineral oil) 260 cases and 73 deaths. These figures suggested that in certain trades there were large numbers of cases which went unnotified, owing to the non-dissemination among the workers of the necessity of getting treatment for a dangerous condition, otherwise it was difficult to explain the disproportionately high death rate to number of cases. He believed that radium offered a probable means of curing the malady or making it less fatal.

After dealing with chrome ulceration, with baker's dermatitis (the number of cases of which he thought might be expected to increase from year to year), and with silicosis, Sir Thomas Legge turned finally to the malady which accounted for the greatest number of compensation payments—namely, miners' nystagmus. In 1927 the number of cases for which compensation was paid was 9,736, in 1,892 of which the first payment had been made during that year. This compared with 2,759 cases of subcutaneous cellulitis of the hand ("beat-hand"), 2,309 cases of "beat-knee," 367 cases of "beat-elbow," 279 cases of inflammation of the synovial lining of the wrist-joint, and 275 cases of lead poisoning and its sequelae. He mentioned that miners' nystagmus had not come within his purview, because his work had been limited to factories and workshops; but he shared the view of Dr. J. S. Haldane and others that it was due to the enormous strain, ending in a psychoneurosis, caused by looking at the non-reflecting coal surface.

JORDANBURN NERVE HOSPITAL AND PSYCHOLOGICAL INSTITUTE, EDINBURGH.

THE one hundred and sixteenth annual meeting of the Royal Edinburgh Hospital for Mental Disorders at Morningside, Edinburgh, was held on February 25th, with the Lord Provost, Sir Alexander Stevenson, in the chair. The report of Professor G. M. Robertson, physician-superintendent, showed that in the institution, including Craig House and West House, there had been under treatment during 1928 a total of 277 voluntary patients and 795 certified patients. During the year 114 voluntary patients were admitted, as compared with 98 under certificate, and the excess of those admitted voluntarily, which has been the rule for several years past, is accepted as a gratifying development, because it is usually accompanied by earlier treatment and by a more willing co-operation on the part of the patient in the measures adopted, transforming the atmosphere of detention into the freer air of the modern hospital. In the six nursing homes which have been established by the managers during the past ten years there had been treated during 1928 a total of 203 patients.

The report deals specially with the Jordanburn Nerve Hospital and Psychological Institute, which has been provided by the managers as a new departure, distinguished from the other institutions already under their management, enjoying the legal status conferred by their new charter, and corresponding in general to that of voluntary hospitals for general physical diseases.

The Jordanburn Nerve Hospital is a one-story building of 50 beds, divided equally between the two sexes. A verandah runs the whole length of the building on the southern side, and faces a garden, two acres in extent, for the provision of the fresh air and sunshine which are essential agents in the treatment of nervous disorders. The entrance is in Morningside Park, which is conveniently situated for access from the city. In order to meet the requirements of nervous patients who can receive treatment and at the same time carry on their duties at home or in the workshop, the managers have built a new out-patient department at a cost of £10,000, where a clinic will be held every forenoon at 10.30, and at other suitable hours. The clinic is intended also to provide Edinburgh with facilities for the performance of the various psychological investigations, examinations, and mental tests that every great city should have at its disposal for its educational, social, and judicial services, and will thus play the part of an important civic institution. The organization of the clinic, in addition to giving advice in psychiatry, will have a mental deficiency department, a department for neurology in which organic nervous diseases and epilepsy will be dealt with, a psychological department for research work, a child guidance clinic, and a social service department, from which workers will visit patients in their homes.

The report points out that the provision of all the necessary machinery for team work under one roof gives the Jordanburn Nerve Hospital a unique position in relation to problems of nervous disorder. Co-ordination of the whole scheme will be effected under the directorship of the physician-superintendent of the Royal Mental Hospital. The work of the out-patient department is intended to be gratuitous, and most of the staff are voluntary workers, but it is hoped that such expenses as are incurred will be defrayed by the public in view of the benefits conferred. As regards in-patients, it is intended that one-fourth of the accommodation shall be reserved for those who cannot pay for treatment. The extent to which the managers will be able to help the poor will depend, however, on the financial support that they receive from the public, and on funds or endowments that may be bequeathed by those who sympathize in the objects of the institution. In the paying wards the rate will be two guineas a week. The teaching of undergraduates is to receive careful attention, and the managers are building a lecture theatre at a cost of £8,000, which is expected to be ready before the beginning of next year. It is intended to use this for classes of medical students, for post-graduate teaching, and for popular lectures of an educational character. It is also intended ultimately to erect psychological laboratories on a site which has been set apart near the hospital, but as the additional cost is expected to be £20,000 the construction has meanwhile been deferred.

Inaugural Dinner.

To mark the inauguration of the Jordanburn Nerve Hospital a dinner was held in the Hall of the Royal College of Physicians, Edinburgh, on February 25th. The MARQUESS OF LINLITHGOW, K.T., presided. Sir WALTER FLETCHER, in submitting the toast of "The Jordanburn Nerve Hospital," said that in the great war he was inclined to think that the medical profession had been better prepared than the military profession, but in one direction medicine had been found wanting, for it had no organized approved scientific system for dealing with war neuroses. The medical profession had not had, in its medical training, any instruction in the processes of the human mind in relation to the machinery of the nervous system, and specialists were at that time torn by acute controversies over what were the best methods of dealing with forms of mental disorder. After the war, however, great gain had come in this particular field of work, and a great wealth of experience had been obtained. In Scotland he believed he was right in saying that over 60 per cent. of all who entered the mental hospitals did so voluntarily and not as certified insane. Edinburgh led the way in respect of its attitude to mental disorders, and

he thought this city was striking out in front of any other civic capital. He thought the present movement was not unworthy to rank with any of the great Edinburgh enterprises of the past. Dr. ROBERT A. FLEMING, President of the Royal College of Physicians, gave details of the inception and history of the Royal Edinburgh Hospital for Mental Disorders, and referred to the many cases in which mental experts failed to make up their minds in medico-legal cases as to whether a criminal was sane or insane; but this new departure which they were celebrating might lead to greater improvement in this respect. Professor LORRAIN SMITH expressed congratulations to the board of management on the foundation of the new institute at Jordanburn, and said that this was one of the few occasions in which, coupled with a hospital which was a place of treatment, there was to be an institute as a place of investigation. The foundation of the institution was a memorable event in the medical school and in the city of Edinburgh. Miss OLGA NETHERSOLE, of the People's League of Health, said she was convinced that what the Government did not spend on adequate housing, education, and protection of workers had to be paid a hundredfold in hospitals, workhouses, asylums, and homes for cripples. There was work for voluntary health organizations in connexion with the prevention of mental breakdown, which was one of the costliest and least hopeful to the national expenditure. This comparatively new branch of medicine must look to research and education for its great advance. Sir ARTHUR H. ROSE, chairman of the Board of Control, in proposing the toast of "The Board of Managers," said that Scotland owed a great deal to the authorities who managed its royal asylums, for without these progress in dealing with the terrible affliction of mental disease could never have been so great in Scotland as it actually was. He thought that the public spirit of the board at the Morningside Hospital had now taken a material step in advance in the treatment of this terrible affliction. Professor G. M. ROBERTSON, in proposing the toast of "The Chairman," expressed his admiration of the work which the board of managers of the Royal Edinburgh Hospital for mental disease had done, and he thought that in the present instance the board was not only keeping in the van, but was doing a valuable work in exploration.

New Zealand.

[FROM OUR CORRESPONDENT.]

Annual Conference of the New Zealand Branch of the British Medical Association.

THIS conference, arranged to take place under the patronage of His Excellency the Governor-General on February 19th and following days, comprises sections of surgery, medicine, diseases of the eye, ear, nose and throat, obstetrics, radiology, psychiatry, and preventive medicine. The programme includes a discussion on cancer, to be opened by Mr. Sampson Handley of the Middlesex Hospital, and keen satisfaction is expressed by members of the New Zealand Branch that he is to honour the conference as representative of the Association. Mr. Victor Bonney's visit last year was most inspiring and instructive, and earned the deep gratitude of the Branch, which is anxious to maintain the closest possible relationship with the parent body. Other features of the conference are a series of surgical operations, clinics, and demonstrations to be held at the Wellington Hospital, and an extensive programme of entertainments, including receptions at the Houses of Parliament and the Viceregal residence. Arrangements have been made for meetings of the New Zealand Fellows of the College of Surgeons of Australasia, to take place on the day preceding the opening of the conference.

Dangerous Drugs.

New regulations have been issued under the New Zealand Dangerous Drugs Act, and the schedule of drugs to which the Act applies has been extended. A medical practitioner in emergency may, orally or by telephone, direct a registered chemist to whom he is known personally to dispense for a patient a dangerous drug, but must forthwith reduce such prescription to writing and transmit it to the chemist. He may only prescribe in any case for the purposes of medical treatment, and must understand that his prescription shall be dispensed only once, though, if he so directs, it may be dispensed on not more than three occasions, at intervals to be specified on the prescription. The chemist must retain such prescription for one year. The various proprietary preparations of heroin *linctus* and syrup cocillana come within the scope of the Act.

Mental Defectives Act.

Some of the provisions of the amended Mental Defectives Act of New Zealand are noteworthy. If any magistrate or justice is of opinion that a person brought before him charged with an offence is mentally defective he shall forthwith advise the chairman of the board, who shall require an investigation of each case to be made by a psychological clinic, the term "mentally defective" including the feeble-minded and the socially defective, and not simply the insane. Every person who, except for medicinal purposes on the written authority of a registered medical practitioner, supplies any intoxicating liquor to be consumed by any mentally defective person registered under this Act commits an offence, and is liable on summary conviction to a fine of fifty pounds. Furthermore, every woman or girl whose name is registered in accordance with the provisions of this Act shall be deemed mentally defective, and every person who has, or attempts to have, carnal knowledge of any such person shall be guilty of an indictable offence accordingly.

Native Medical Practitioners in Fiji.

Suva, the centre of the South Pacific, has had a system of training native medical practitioners, but by the aid of the Rockefeller Institute this system is to be developed and extended. The problem of giving medical aid to native populations is one of method and of finance. The annual expenditure of training native doctors for Fiji and the islands in the vicinity is likely to be about £3,300; the cost of the buildings and plant is £8,000. A tutor who came from Aberdeen University has been appointed, and will take charge of the main part of the practical teaching, and Government medical men and resident scientific officers will take charge of the more specialized teaching. The course is a three-year one, and forty students, chosen by competitive examination, and young men of high intelligence and good physique, will be trained without cost to their parents. When their training is complete they will be sent to various districts and given a salary ranging from £45 to £150 a year. They also will be given quarters, and, where there is no fully qualified doctor, will be allowed the right of private practice. When the scheme has developed arrangements will be made for post-graduate training.

Ireland.

Goldsmith and Medicine.

GOLDSMITH and his connexion with the medical profession was the subject of a lecture given recently at Trinity College Medical School, Dublin, by Dr. T. P. G. Kirkpatrick, honorary lecturer in the history of medicine. There was a large attendance. The Provost was in the chair, and, in opening the proceedings, said when they were celebrating the bicentenary of Oliver Goldsmith's birth last term he did not remember that anyone had said anything about Goldsmith's connexion with medicine or of his being a medical man. He did remember an examination paper which said: "Goldsmith at once took out a medical degree, but had no practice, and never had any patients but one—and that was himself, and he nearly killed himself—the only patient he had; and after that," the writer added, "he took to literature." Goldsmith's association with the medical profession was a phase of that great man's life which Dr. Kirkpatrick would deal with. He said that Goldsmith entered Trinity College as a sizar at the age of 15 on June 11th, 1745. Both as a child and a schoolboy he was said to be dull and stupid, but the fact that at 15 years of age he had learned enough Greek and Latin to pass the entrance examination to

Trinity as a sizar did not lend much support to that view. There were no contemporary records of Goldsmith, such as they had of his contemporary and great compatriot Burke, who, though a fellow student, did not seem to have known him; nor did Goldsmith seem ever to have joined Burke in the debates of the Historical Society. That Goldsmith's life in college was miserable was unlikely from all that was known of his character. He left college with a competent knowledge of the classics, and also with a much wider knowledge of life than was usual for one who had just graduated. A man who had sold his bedclothes to shelter the derelict might well have learned more of the problems of life than the scholar whose polished periods were to procure for him a bishopric. They had not a trace of evidence that Goldsmith had any idea of following the medical profession until shortly before he set out for Edinburgh, in the autumn of 1752; nor, indeed, was there any evidence that he ever returned to Trinity College after he took his degree in 1750. Although Goldsmith had referred to the lecturers and professors in Edinburgh, he never mentioned any medical lecturer in Trinity. There was no evidence that Goldsmith, when he started the study of medicine, did not intend to become a doctor. He attended with considerable regularity lectures in Edinburgh, but it seemed strange that he should have left Edinburgh without taking a degree in medicine. At that time there was no strict curriculum or regulation for candidates seeking medical degrees, since the statute which afterwards governed such matters was not formulated till 1767. It must be remembered, however, that at Edinburgh University it was then the exception rather than the rule for students to proceed to a degree either in arts or medicine. It could not be assumed, the lecturer went on, that Goldsmith did not intend to pursue the practice of medicine because he did not seek a degree in Edinburgh, or that his studies there had not qualified him to do so. From Paris Goldsmith went to Berne, Basle, and Geneva, and thence into Northern Italy. He was reported to have spent some months in Padua, where it was suggested he took a medical degree. For this suggestion there was no evidence, nor was there any that the University of Padua granted the degree of Bachelor of Medicine at all. Having referred to Goldsmith's return from the Continent to England, Dr. Kirkpatrick went on to say that some time subsequently his old friend and fellow student at Edinburgh—Dr. Fanu Sleigh—met and assisted him to start in medical practice in a small way at Bankside, in Southwark, and that, writing in reference to this, Goldsmith said: "By a very little practice and a very little reputation as an author I made a shift to live." The little practice in medicine gave him ample time, however, for writing. Through the acquaintance with Dr. Milner, one of the most interesting episodes in Goldsmith's medical career occurred—his proposed appointment as medical officer in the East India Company at Coromandel, for which he had the more or less definite promise of an appointment at £100 a year, with the prospect of a private practice, that was believed would bring it up to £1,000. After the offer was postponed, the idea was ultimately cancelled by the Surgeons' Hall on the ground that he was not qualified. The cause of this rejection was not recorded. On March 31st, 1763, Goldsmith signed an agreement with James Dodsley, the publisher, to write a book called *A Chronological History of the Lives of Eminent Persons of Great Britain and Ireland*. In this agreement, written in his own hand, and preserved in the British Museum, Goldsmith describes himself as "Oliver Goldsmith, M.B." As far as was known this was the first occasion on which he was recorded as a bachelor in medicine, although it was not uncommon to find him referred to as "Doctor Goldsmith," or described as "Oliver Goldsmith, M.B." It was reasonable to suppose that in describing himself in an official document as "M.B." Goldsmith did so correctly, and that at that time he had, in fact, been granted that degree. The records of many universities had been searched, but in none had there been found any documentary evidence for a degree in medicine granted to Goldsmith. If it was so, he must have been granted it *in absentia*. Furthermore, it must have been given by the special grace of the board, without the performance of the usual acts. Dr. Kirkpatrick then referred to a subsequent attempt of Goldsmith to supplement his income by medical practice, and how it ended, and he concluded with a description of Goldsmith's death in 1774.

Medical Practice in the Free State.

An interesting discussion was held in Dublin on February 22nd, when Dr. J. P. Shanley read a paper on the State and medicine to a meeting of the Section of State Medicine of the Royal Academy of Medicine in Ireland. Dr. Shanley remarked that the Medical Act of 1858 did not, unfortunately, restrict the practice of medicine to those on the *Register*, and that even to-day anybody who so wished could treat cancer of the stomach with herbs, replace an alleged dislocated vertebra, "cure" diphtheria, or prescribe glasses for acute glaucoma. Indeed, in view of certain recent legal decisions, such a quack appeared to be in a safer position in the case of an action for malpraxis than a legally qualified and duly registered practitioner. The right to sue for fees was of little value, since medical men did not often wish to take this course. Dr. Shanley thought that a profession which gave so much gratuitous and unstinted service to the State deserved better treatment from it. With the coming of the national insurance scheme the State had taken a really big step forward in the control of the profession; but, while such a service might possibly be a good method of overcoming difficulties in Ireland, care would have to be taken to avoid an excess of bureaucratic interference. The control of merely medical matters should be in the hands of the medical profession. Although the Irish Public Health Council in 1920 had reported strongly in favour of a State medical service for Ireland, the Free State Government had not yet attempted to establish it; the Local Authorities Employees Act was, however, a courageous effort to abolish abuses which had prevailed under the old system of medical appointment. The president, Professor J. W. Bigger, who followed, suggested that a State medical service would benefit doctors by introducing the possibility of promotion. The selection of candidates by the local appointments commissions seemed now to be working well and to be as fair as possible. Complaints were often received from candidates, however, that they had to pay a fee on each application, and were often obliged to travel long distances for an interview; the president thought it ought to be quite possible to remedy these grievances. The ensuing discussion turned largely on possible improvements in the working of the appointments commissions. It was suggested that the various kinds of appointments might be graded, so as to make it easier to attract in each instance the most suitable type of medical practitioner, and to facilitate promotion as the reward of merit.

County Wexford Medical Practitioners.

At a recent meeting of the medical practitioners of county Wexford it was decided that the county board of health be informed that the dispensary medical officers had decided not to accept a lower fee than £6 6s. a week for locumtenent work. It was also decided that the Irish Medical Secretary should be asked to forward copies of the decision of the meeting to those doctors who were absent, for their signatures. In consequence of the repeated refusals of the health board to increase the salaries of the Enniscorthy Union medical officers of the county home the meeting decided to appeal to the Department of Local Government and Public Health to fix an increased scale by sealed order. Dr. O'Brien, surgeon to the county hospital, thanked the health board for considering the draft regulations for the treatment of private patients in the county hospital. The board's suggestion that it should arbitrate in cases of dispute between the surgeon and patient, and that the decision should be final, might work out satisfactorily, but he regretted he could not fall in with the view for the following reasons: (1) the arbitration court was not fairly constituted; (2) the members of the health board were not permanent; (3) it would not be just or loyal to his colleagues. He was prepared to adopt the draft regulations in their original form supplied by the Department of Local Government and Public Health, and thus bring to a close an unpleasant controversy.

Scotland.

Presentation to Sir Leslie Mackenzie.

At a luncheon held in the North British Hotel, Edinburgh, on February 23rd, in honour of Sir Leslie Mackenzie and Lady Mackenzie, a portrait of Sir Leslie Mackenzie, by Mr. Henry W. Kerr, R.S.A., was presented to him. At the luncheon he was the guest of the Society of Medical Officers of Health and of the Scottish Society of School Medical Officers, and the chair was occupied by Dr. Thomas Adam, president of the former society. Dr. A. K. Chalmers, lately medical officer of health for Glasgow, proposed the health of the guest, and said that it was their desire to recognize the excellence of his work as medical member of the Board of Health for Scotland. Four movements had impressed themselves indelibly on the development of the public health services during the first quarter of the present century. Inquiries into the physical training of school children had formed a special subject of attention by Sir Leslie Mackenzie and Dr. Matthew Hay of Aberdeen, and this subject had now become the physical education of the school child, as a natural expansion of the maternity and child welfare movement. The tuberculosis movement, again, from modest beginnings towards the end of last century, had expanded in time to the institutional treatment of this disease. Venereal diseases, also, which caused much untold misery to mothers and children, had raised in an acute form the responsibility of the State as the guardian of future generations. The fourth great movement had been in relation to housing. All these movements reflected a wide change in public thought, and had become the expression of a public health conscience. With this work Sir Leslie Mackenzie had been intimately and honourably associated, and for this reason they were doing honour to his work. Sir Leslie Mackenzie, in replying, said that no meeting in Scotland could give him more profound satisfaction than one at which he met friends and colleagues, and which represented every phase and stage of his work in the public health and school health administration of Scotland. He said that in 1901 he took office as the first medical inspector under the Local Government Board, and he proceeded to comment on the special movements that had been inaugurated during his period of service. In 1906, he said, they had hardly a single bed for tuberculosis, and to-day the accommodation for these patients approached 5,000. The Royal Commission on Physical Training had appointed Professor Matthew Hay and himself to examine 1,200 school children, of whom 600 were in Edinburgh and 600 in Aberdeen. From this narrow sample he had felt justified in concluding that nothing short of systematic medical inspection gave any hope of improvement, and he made that recommendation explicit in his report. In 1903 the Houses of Parliament had declared strongly in favour of medical inspection, and for three years he had spent a great deal of his time in lecturing upon this subject. The medical profession were not at first favourable, but the younger generation saw that they had at last succeeded in bringing clinical medicine on to the preventive plane. The true initiative in establishing medical inspection rested with the late Sir Henry Craik, and to him, as well as to Sir John Struthers, his successor, and Sir George Macdonald, we owed the splendid system that held within it so many active minds at the present time. Twenty-five years ago everyone was speaking of infant mortality, and to-day people spoke of child health or child welfare and maternity service. Here also he had had an opportunity of playing a certain part. In the year 1915–16 he was asked by the Carnegie Trustees to prepare the Scottish Report on Scottish Mothers and Children. It was gratifying to find that after twelve years the report was still asked for; it had circulated largely in America, and he knew that many workers had found it of some value. The Royal Commission on Housing, known as the Ballantyne Commission, was, he thought, the most important that had sat in Scotland for over a hundred years. The late Mr. Gillespie and he had drafted a clause applying the conception of a nuisance clause under the Public Health Act to the provision of housing, and this became the fundamental proposition in the 1919 Housing Acts of England and Scotland. The result to-day had been that in England there were, he believed, nearly 1,000,000 new houses, and in Scotland the first 100,000 houses were safely on the way to erection. This social revolution had centred on the point that the local authorities had been obliged first to survey their districts by seeing that the people were properly housed, and secondly to provide houses. Speaking of the civil service, he said that it was constantly subjected to attack, but although no one pretended that the service was perfect, he had been convinced by twenty-seven years as a member of it that it was in a thousand ways a magnificent service. Lady Mackenzie also received a presentation, for which she briefly expressed her thanks.

Glasgow Royal Asylum.

The annual meeting of contributors to the Glasgow Royal Asylum was held on February 21st, with the Lord Provost, Sir David Mason, in the chair. The physician-superintendent, Dr. D. K. Henderson, in his annual report, stated that the total number of patients under treatment during the past year had been 653, including 135 new admissions. Of the 117 patients who had been discharged, 45 had recovered. The death rate had been 4.7 per cent. of the average number resident. The voluntary form of admission was being more widely utilized, as shown by the fact that 68 of the patients admitted entered the asylum in this way. Dr. Henderson, in drawing attention to some of the social implications of mental disease, pointed out that the 1927 report of the General Board of Control for Scotland showed that there was one certified mental patient to every 264 of the population. If to this figure was added the number of voluntary patients, of mental defectives, and of criminals in whom mental disorder and defect were present, a still better idea of the significance of mental illness to the health of the community was obtained. This problem was becoming more insistent because there was a steady increase in the numbers requiring institutional care, and the problem had now become one of prevention. Twenty years ago it was reckoned that 40 per cent. of the admissions to mental hospitals were directly or indirectly due to alcohol or syphilis, but this was hardly true to-day, for there had been a notable decrease in both these causes, and the public was gradually evolving a better moral standard in regard to them. The problem to be faced now was more social than medical. The common factor in the associated problems was that they had to deal with unstable, difficult, ill-balanced personalities, and investigation showed that such maladjustments had their beginning not late in life, but in infancy or adolescence. In the past the worst cases had been segregated in institutions, the less gross were educated in special schools, and in addition there was the much more difficult problem of making provision for and helping those whose defects were not due so much to hereditary influences as to unhealthy environment. The establishment of child clinics, which had taken place already to a considerable extent in the United States, was very important in relation to this matter. The purpose of such clinics was the individual study and treatment of children who were failing to adapt themselves to any aspect of life. Here the aim should be to develop agencies and clinics whereby touch could be established with such children before their habits became set. Such an organization demanded a staff of psychiatrists, psychologists, and social workers to deal with patients in their own homes. To a certain extent this need was already met by psychiatric out-patient departments attached to general hospitals, but these departments were not yet sufficiently organized to take the place they ought to take in the life of the community. The Lord Provost, in moving the adoption of the report, said that if the advantages of the voluntary system of admission were better recognized there would be fewer cases of chronic insanity, and Colonel J. A. Roxburgh, in seconding, said that the directors of the institution were anxious that the public should regard it no longer as a place of detention, but as a place of cure.

Western Infirmary, Glasgow.

At the annual meeting of contributors to Glasgow Western Infirmary, held on February 22nd, the Lord Provost, Sir David Mason, announced that a gift of £5,000 had recently been received by the Infirmary from Sir Henry and Lady Mechan, for the purpose of purchasing radium for the early treatment of cancer. In drawing attention to the deficit on the year's working of over £12,000, which was due largely to the increased number of patients treated, the chairman suggested that there was room for improvement in the subscriptions given by some of the warehouses, shops, and offices in the city. He also pointed to the fact that during the year 300 cases of motor accidents had been dealt with in the Infirmary, and he saw no mention in the report of any contribution from persons treated on account of these accidents. Colonel John A. Roxburgh, in seconding the report, said that they would be glad to see the gap between ordinary income and ordinary expenditure filled up, although the financial position of the Infirmary was still satisfactory. He referred to the rapidly increasing scope of radium therapy and the encouraging results which were being obtained in certain cases of malignant disease, which made the recent gift of radium to this hospital highly acceptable. Research work on cancer had been carried out in the laboratory of the Infirmary through the benefaction of the Robert Donald Trust, and the radium would be under the charge of the Donald Research Scholar for Cancer, Dr. A. A. Charteris, who was making a special study of this form of treatment. It was not proposed to limit the benefits which would accrue under this scheme to hospital patients only, and any of the radium which was not in use in the Western Infirmary would be available to the hospital staff, by special arrangement, for the treatment of private patients.

Leith Hospital.

At the annual meeting of Leith Hospital an appeal was made by the chairman, Mr. John A. Lindsay, for a supply of radium, which was urgently needed for the treatment of certain cases of a grave or hopeless nature. He also stated that it was desirable to take advantage of the reconstruction that was at present going on in the vicinity of the institution to secure adjoining ground so that there might be more air space round the hospital. Mr. Ernest Brown, M.P., in seconding the report, said that it would be a mistake to suppose that because a greater concentration of the public health services was taking place at the present time, there would not be as much need for private and individual work in connexion with hospitals, such as Leith Hospital, in the future. With the inauguration of new efforts there would be more scope for the work of voluntary hospitals as time went on.

Red Cross Work in Edinburgh.

The annual meeting of the Edinburgh Branch of the British Red Cross Society was held on February 28th. Lord Provost Sir Alexander Stevenson presided. The chairman remarked that there had been an excellent record of beneficent work performed by the Red Cross since the war as well as during the war years. Its members, drawn from all classes, had performed deeds of bravery and unselfishness which commanded the admiration of the world, but even in time of peace the Red Cross Society had a great work to do. With regard to the society's work on behalf of the miners' fund, he said that they had reached no less a sum than £31,000, and it had been a great satisfaction to him that the Red Cross Society had formed a depot to receive gifts of clothing from which about 27,000 articles had been distributed. The county director's report showed that enrolments of members for the Voluntary Aid Detachments continued to progress. In Edinburgh the membership now consisted of 120 mobile members, 122 immobile members, and 37 probationers, who displayed a satisfactory standard of efficiency on examination. It was stated that during the recent influenza epidemic the Scottish nursing service would have been defeated in its work if it had not been for the great assistance given by members of the Red Cross.

Central Midwives Board.

At a meeting of the Central Midwives Board for Scotland, held for the election of the office-bearers, Dr. James Haig Ferguson (Edinburgh) was unanimously re-elected chairman, and Dr. Robert Cochrane Buist (Dundee) was re-elected deputy-chairman. The meeting appointed other committees, and also examiners for the ensuing year, and approved and revised, subject to inspection by the board, institutions applying for recognition under the new regulations, with the teachers attached thereto, for the training of midwifery nurses.

Correspondence.

VOLUNTARY HOSPITALS IN SCOTLAND.

SIR,—The report in your issue of March 2nd (p. 413) of the meeting of the Scottish Regional Committee of the British Hospitals Association calls for some comment, as it does not represent the actual position of matters. To enable this to be done the following facts must be kept in view.

In 1927 the central office of the British Hospitals Association sent to the Scottish Regional Committee a series of inquiries, asking for their opinion on them. A meeting was held in October, 1927, for the consideration of these inquiries, but they were never discussed. The Regional Committee decided to set up local committees in the five regions of Scotland, who should explore the needs of their respective areas and consider the possibility of co-operation between the statutory authorities and the voluntary hospitals. Further, it decided to approach the Secretary of State for Scotland, asking him to receive a deputation of representatives of the leading hospitals to discuss the position and ask for his view on the lines along which the hospitals authorities should proceed in co-operation. It was also resolved that another meeting of the Regional Committee should be held in Glasgow to receive and consider the report of the deputation to the Secretary for Scotland.

The Secretary for Scotland agreed to receive the deputation on December 9th, 1927. This meeting took place, and at it the Secretary for Scotland appointed a Liaison Committee to be a channel of communication between himself and the voluntary hospitals, the Liaison Committee to ascertain the views of the voluntary hospitals in the respective areas that the committee represented.

Although it had been decided at the meeting in October, 1927, that another meeting of the Regional Committee should be held in Glasgow, to receive the report of the deputation to the Secretary for Scotland, this meeting was not held until February 29th, 1928. At this meeting it transpired that the Liaison Committee had never taken any steps to ascertain the views of the voluntary hospitals in their respective areas on the changes proposed in the Local Government (Scotland) Bill. What, apparently, it had done since its formation was to assume executive powers, and, as one of its members stated, "to be actively engaged in drafting proposals for the Local Government (Scotland) Bill"; and this was done without consulting the voluntary hospitals in their respective areas. The outcome of this has been that a clause, drafted by the Liaison Committee after subsequent meetings with the Scottish Health Department, and intended to safeguard the interests of the voluntary hospitals in any co-operation with the municipal hospitals, was not accepted. It might have been different had the committee had behind it the weight of the opinion of the voluntary hospitals; and, from the report in your columns, one of the members of the Liaison Committee now admits that the Liaison Committee in the role it has assumed "could be effective only if it had behind it an informed body of opinion." Not having this, the result was bound to be what has taken place, and the whole question of the relationship between the statutory authorities and the voluntary hospitals has been decided, not on the views of the latter, but on the opinions of the individual members of the Liaison Committee.

It is only right that the medical profession in Scotland should know exactly what has happened, and what has brought it about. Already there has appeared in Glasgow a protest against what has occurred, and the Scottish Regional Committee at its last meeting passed a mild censure on the Liaison Committee when it pointed out that "it would be desirable to have the views of the areas co-ordinated before they went forward to the Liaison Committee, for it would be unfortunate if different views were put forward from the various areas on any particular subject."

At the recent meeting of the Scottish Regional Committee it was thought that the Regional Committee of the British Hospitals Association was the best body to concentrate the opinions of the voluntary hospitals, and it is quite clear that the Scottish Regional Committee is being used as a stalking horse to shelter this attempt to gain control over the voluntary hospitals in Scotland. Such a role is not the function of the British Hospitals Association; it was established to consider *questions in connexion with the management of the hospitals*, but it was not intended to have any say in what would be called *hospital policy*.

One unfortunate outcome of these efforts of various bodies to be the dominant factor in controlling the voluntary hospitals is to undermine the voluntary principle in connexion with hospitals services, and to weaken it instead of strengthening it. What is really needed is an independent central body elected by the voluntary hospitals themselves, and representative of their views.—I am, etc.,

Glasgow, March 4th. GEORGE THOS. BEATSON.

THE AFTER-EFFECTS OF RADIUM TREATMENT.

SIR,—The following account of the after-effects of radium therapy in patients treated by me at the Christchurch Hospital and privately is given in the hope that it may stimulate other workers to report their own experience of mishaps that may follow this form of treatment. It is a subject on which I am often asked questions by my colleagues in New Zealand.

Untoward sequels of radium treatment may be divided into excessive skin reactions, fibrosis of deep tissues, increased pain, and mental or psychical changes. An overdose of radium used externally may be followed by telangiectasis, scarring, and loss of hair, but these should not occur with ordinary care, and are no longer seen in the *x*-ray clinic. Telangiectasis may be unsightly, but if a malignant growth has been destroyed the scarring is a small disability compared with the destruction that would have occurred if no treatment had been used. It has been stated that treatment with radium or *x* rays before operation may embarrass the surgeon by formation of fibrous tissue, but as this treatment should only be given a few days before operation the difficulty should not arise.

My follow-up reports give no indication that increase in pain occurs in the majority of cases after radium treatment. Certainly in external cancer the patients often tell me that the pain has been absent after the first application, but in uterine cases I have records of pain occurring in the hips, groin, back of leg, and in the lumbar spine. All these cases have been re-examined, and my notes show that pain had been present before the use of radium, and pelvic or *x*-ray examination showed metastasis in the soft tissues or bone.

The mental after-effects of radium are at present undetermined, and I can find no statement about them in the literature. Experiments by Horsley and Finzi on the effect of radium applied directly to the brain tissues in animals showed vascular changes, but no change in the neuroglia or nerve cells. The conclusion drawn was that the nerve tissue was relatively insensitive, and that vascular disturbance accounted for nerve derangement after the application of radium.

An elderly man was sent to me for treatment of a huge crater ulcer on the right parietal area. The whole of the bone beneath the crater had been destroyed, and the brain was visible. With much hesitation I buried radium round the edges of the ulcer for twenty-four hours, and some weeks later I found that the growth was apparently arrested. No complaint of headache was made, and no nerve symptoms ensued. I have had two other cases in which the bone over the brain was thinned out and the growth was treated with buried needles without any cerebral symptoms following.

In contrast an elderly patient came for treatment with a small papilloma and a small patch of keratosis on the side of the forehead. These were treated simultaneously with a radium plaque applied over a piece of lead rubber, in which holes had been cut to expose the two areas. Both lesions disappeared after one treatment of ninety minutes. About six weeks later I heard that the patient had developed aphasia, which lasted about a fortnight. I was asked if this might be due to the radium, and expressed the view that it was merely a coincidence.

During the same month I was asked to treat a middle-aged lady for menorrhagia. The patient did not come for treatment, and a few hours later her medical attendant telephoned to say that she had had a "stroke." Had the stroke occurred after the introduction of radium the treatment would inevitably have been held responsible.

In this hospital and in private practice I have treated 66 patients for malignant disease of the uterus, 68 for menorrhagia, and 7 for fibroids. Every case has been carefully followed up, and two of the menorrhagic cases have been reported as suffering from mental symptoms. The superintendent of the neighbouring mental hospital, to whom I referred the question, stated that he had no record of any case in which radium was suspected as being the cause of mental breakdown.

I think that the extraordinary success of radium treatment in the uterine haemorrhage of middle life must be due to the action of the gamma rays upon the ovarian tissue, causing a practical castration. I can see no other explanation why long-standing haemorrhage should cease with such dramatic swiftness. Does this radium castration prove more dangerous mentally to the patient than oophorectomy or than the slower atrophy of age? In males the operation of vasectomy in cases where patients were unable to undergo prostatectomy was supposed to be followed by rapid senile decay. Prior to 1914 I had performed vasectomy on a number of old men who were unfit for operation, but in no case did senility follow. Castration in young males does not apparently damage the mental powers. The history of eunuchs who rose to political prominence in the Eastern empires suggests that a castrated male is not below the average in brain power.

For the treatment of menorrhagia we use as a routine dose 50 mg. of radium element in platinum tubes (wall thickness 1 mm.) enclosed in rubber drainage tubes 1 mm. thick, and placed in the uterus for twenty-four hours, the total dose being 1,200 milligram hours. We have not yet had a case in which the haemorrhage did not cease. Every patient is warned that menopausal symptoms will occur, and my follow-up reports show that all experienced hot flushes, sweating, headaches, etc.

I am unable to say whether these symptoms are more pronounced in radium patients than in women passing through the normal climacteric, but the fact that two patients treated for menorrhagia have developed mental symptoms makes me anxious to learn from other radium workers if they have similar records. I would feel sorry to refuse treatment to a woman suffering from violent long-continued haemorrhage for fear that the treatment may be followed by mental catastrophe, and it would be a satisfaction if the experience of other hospitals in this matter could be obtained.

It is known that surgical operations on the uterus and ovaries may be followed by mental breakdown; I have seen insanity follow hysterectomy. In other regions surgery has been blamed for mental troubles. Recently a patient under my observation committed suicide after operation for hyperthyroidism, yet it would be incorrect to quote this as the result of a skilfully performed operation.

I have always been averse to using intrauterine radium applications in any but middle-aged women. In two cases recently I consented to use this treatment in women under 30 suffering from severe and long-continued haemorrhage that medical treatment and curetting had failed to relieve, but I gave only one-third of the routine dose. Sufficient time has not elapsed since treatment to report whether normal menstruation has reappeared.

I have so far declined to use radium for dysmenorrhoea, but I think that if the patient is going downhill into chronic invalidism it might be justifiable to use a small dose of radium in the hope that temporary cessation of the painful periods would be followed by a normal flow. I am

aware that many of these cases are of nervous origin, but, even so, temporary relief might be the means of regaining normal mental balance.—I am, etc.,

P. CLENNELL FENWICK,
Officer in charge, Radium and Deep Therapy Department, Christchurch Hospital.
Christchurch, New Zealand.

LOCAL ANAESTHESIA IN OPERATIONS FOR HAEMORRHOIDS.

SIR,—Dr. T. H. T. Barber's communication published on March 2nd (p. 397) will help to dispel the widespread but very antiquated belief that the removal of piles is followed by days of such pain and discomfort that the ordeal is scarcely worth while. Under modern conditions the operation is one of the most gratifying and satisfactory in surgery; the much-dreaded after-pain and discomfort have been reduced to a minimum, and, in fact, have been rendered quite negligible. The only criticism I venture to offer to Mr. Barber's remarks is that he did not sufficiently emphasize the practical simplicity of his own admirable recommendations.

I have employed local anaesthesia for the removal of piles for the last twenty years; 1/2 per cent. novocain solution, to which adrenaline (supplied in ampoules) is added, is usually at hand and acts as perfectly as more complicated preparations. The skin round the anal orifice is very thin and if a fine dental needle is used the whole circumference of this area can be anaesthetized in five minutes without the knowledge of the patient. Deep infiltration is unnecessary. The sphincter becomes gradually relaxed; it should not be forcibly stretched. I have come to regard stretching of the sphincter, no matter how thoroughly, as one of the causes of after-pain and one of the determining factors in producing transient retention of urine. A triangular mosquito forceps applied to the anaesthetized skin provides a traction handle for the extrusion of the pile-bearing area.

I am not wedded to any particular form of operation, but I rather favour a modification of the much-maligned Whitehead method. Modern technique has made it a safe and satisfactory procedure, when the indications are present. With local anaesthesia it is seldom necessary to ligature or clip a single vessel during the preliminary dissection. After removal of the pile-bearing area on each side the sutures are introduced in the manner recommended by Mitchell. A well-trained sister and a Reverdin's needle expedite this part of the procedure. Great care is taken to bring skin and mucous membrane neatly in line. The external sphincter is visualized without difficulty, especially if a head light is used. No skin is removed. The line of suture is smeared over with bipp and a generous dressing of sterilized vaseline applied. A tube is inserted, but in a few cases owing to discomfort needs early removal.

Local anaesthesia, asepsis, and accurate suturing have placed the operation for removal of piles in the realm of minor surgery. I have under my care at the moment a patient who told me that for ten years he had abandoned all his favourite outdoor recreations owing to trouble from piles; he was urged not to face an operation with its aftermath of torture. He now knows better, and during convalescence hopes to square accounts with his persuasive but deluded friends.—I am, etc.,

Dublin, March 3rd. W. I. DE C. WHEELER.

SIR,—I can thoroughly endorse Dr. T. H. T. Barber's plea in the *Journal* of March 2nd for the use of local anaesthesia in operations for haemorrhoids and anal fissure. One very great advantage of local anaesthesia is the absence of post-anaesthetic vomiting, which, after general anaesthesia, is a common cause of perianal swelling and oedema.

Dr. Barber describes a technique in which the anal canal is anaesthetized by novocain applied on pledgets of cotton-wool, then a series of subcutaneous perianal injections is given, and finally an infiltration of the sphincter muscle by six or seven injections. In all he appears to puncture the skin about twelve to fifteen times. I can recommend the following technique as being simpler, very rapid in its action, and one which avoids distortion of tissues in the operation area.

The solution is a 1 per cent. solution of novocain (1½ oz.) to which 6 drops of adrenaline (1 in 1,000) are added immediately before use. With the patient lying on his right side and the knees well drawn up, a wheal is raised in the middle line one inch behind the anus. Next, using a 10 c.cm. syringe and a two-inch No. 20 Record needle, and with the left forefinger in the rectum, 10 c.cm. of the solution is injected deeply in the middle line posterior to the rectum. The solution is slowly injected as the needle is advanced. The syringe is then refilled, and 10 c.cm. is injected deeply into the sphincter on the left side; the left forefinger puts the sphincter on the stretch, and the solution is injected as far forwards as the two-inch needle permits. This point in practice is level with the anterior margin of the anus, or even slightly beyond it. The right side of the sphincter is treated in a similar manner, 30 c.cm. of the solution being used in all. The entire injection can be done rapidly through the single point of puncture posteriorly. The anaesthesia develops immediately; the patient can be placed at once in the lithotomy position, and the operation proceeded with. Complete relaxation of the sphincter is obtained, and a perfect anaesthesia for any local operation can be relied upon. In some cases, if a large external pile needs removal anteriorly, a few extra drops of anaesthetic solution may be injected subcutaneously in front of the anus.

I have used this method as a routine for all pile and fissure cases, and have found it useful for other local conditions. There have been no complications, post-operative pain has not been marked, and the patients have invariably been grateful for the employment of this type of anaesthesia. Furthermore, it renders radical operation possible and safe in subjects who, from age or intercurrent conditions, would otherwise be debarred from operation.—I am, etc.,

London, W.1, March 4th. W. B. GABRIEL.

VACCINATION IN THE LIGHT OF RECENT EXPERIENCE.

SIR,—There may or may not be confusion in the statistics coming from Northern Rhodesia and other countries, but the very definite statement was made in the *Monthly Epidemiological Report* (February 15th, 1928), issued by the League of Nations, that "small-pox of severe type appeared in June, 1927, in Northern Rhodesia, where ordinarily only the mild Kaffir-pox is met with," and certain figures were given. But it was not stated whether the Kaffir-pox had disappeared or whether it still continued side by side with the severe form. My letter in the *Journal* of February 16th (p. 319) was written in the hope that more information on the nature of small-pox in Rhodesia would be forthcoming. Meanwhile it is interesting to note that there has been a revival of small-pox, of moderately severe form, in Northern Rhodesia. In the *Times* of February 9th there is a quotation from the weekly bulletin of the Health Section of the League of Nations for February 8th, in which it is stated that "small-pox is widespread in Northern Rhodesia, 4,235 cases with 301 deaths having been reported since the beginning of the year." It is surely worth while to investigate the behaviour of a disease which, in the course of a little over two years, presents a varying fatality rate, which, beginning at 3 per cent., rises suddenly to 20 per cent., dies down to 5 per cent., and again rises to 7 per cent. at the end of the period.

I think Dr. Garrow has misunderstood the object of my suggested test. I agree with him that "it is reasonable to suppose that small-pox and alastrim would confer immunity against each other"; that is, if alastrim is a variant of small-pox. But if alastrim is quite a different disease from small-pox, then it is reasonable to suppose that the one will not protect against the other.—I am, etc.,

Hemingford Abbots, March 3rd. E. W. GOODALL.

A NEW METHOD OF APPROACH IN GASTRIC SURGERY.

SIR,—I feel that the statements made by Mr. Digby Chamberlain (February 23rd, p. 343) under the above heading call for some comment from the radiologist's point of view. Mr. Chamberlain describes the results of two inoperable cases of carcinoma of the stomach and operable dimensions by a large single dose of *x* rays. The rays were applied directly to the tumour at the exploratory operation, the object being to avoid damage to the skin.

It is unfortunate that Mr. Chamberlain has not given radiologists more definite guidance in the matter of dosage. All that he says is that deep x rays were applied in one case for forty, and in the other for thirty, minutes. He does not state the focal distance, the milliamperage, the secondary voltage (minimum wave-length), or the filtration. Nor does he give any quantitative measurement of the dose in recognized units, such as X, H, the French R, or the German R. It is hardly an exaggeration to say that to state the dose in terms of time alone is just as inadequate as it would be to express the dose of morphine according to the number of seconds occupied in its injection.

Since, however, Mr. Chamberlain uses the word "deep" it may be presumed that he means a voltage of at least 150 kV filtered through at least 0.5 mm. Cu., and his main contention is that the dose which was administered could not have been applied transcutaneously without the risk of damage to the skin. Now under these conditions, using a double coil with a focal distance of 28 cm., the tube giving 2 ma. (the usual output over a long period), thirty-five minutes gives approximately 16X, a dose which, at this filtration, causes a barely perceptible erythema, if any. The exposure can be prolonged considerably further before the skin is seriously damaged. It is therefore very doubtful whether the risk of damage to the skin is as great as Mr. Chamberlain fears, and whether he has gained anything by avoiding the transcutaneous route.

Moreover, by this method only one portal of entry is, from the nature of the case, possible, whereas by the ordinary method several may be used. But Mr. Chamberlain has no use for the cross-fire method. He states that "experience shows that one big dose is considerably more efficacious than a number of smaller applications applied to the growth at intervals by the cross-fire method." Here Mr. Chamberlain is confusing two things—(1) the use of several portals of entry at one sitting or on consecutive days, (2) the repetition of the dose at intervals. As regards the first point the advantage of the cross-fire method is not a mere matter of opinion, but is a fact capable of mathematical determination in terms of quanta of energy, and of experimental proof by means of the iontoquantimeter. As regards the second point, the confident statement that the single dose is superior to the repeated dose may represent Mr. Chamberlain's experience as a surgeon, but it is one which the great majority of radiologists will regard as at least very much open to question.

As a matter of fact, radiotherapy after "exteriorization" of the stomach has been practised by Finsterer in 19, and by Werner in 48, cases, and in spite of one case of apparent disappearance of the tumour recorded by the latter it has never been demonstrated that this procedure is superior to the ordinary method.

Cases of gastric carcinoma are so distressing that the appearance of any new and promising method is welcome, and no one would wish to grudge Mr. Chamberlain his success in his two cases. At the same time, one cannot help feeling that real advance in this subject can only be born of clear thinking and accurate measurement.—I am, etc.,

Cambridge, Feb. 28th. FF. ROBERTS, M.D., M.R.C.P.

THE CIRCULATION UNDER THE SPHYGMOMANOMETER CUFF.

SIR,—Dr. Harrington Sainsbury and I seem agreed that the blood is a colloid and incompressible, but we are not agreed that the five inches of the brachial artery under the cuff remain full under a pressure sufficient to obliterate the pulse at the wrist. If the pressure in the cuff be quickly raised, as it usually is, and should be, the pressure soon exceeds that of the blood in the artery, and the blood, being a liquid, is bound to move on to a lower pressure level. No doubt when the pressure is reduced so as to give the systolic and diastolic pressures, the artery fills up; that this filling up is a gradual process is shown by the movement of the lever from the systolic to the diastolic pressure. As to the effect of a rigid artery in apparently raising the blood pressure, this would no doubt occur with a perfectly rigid artery, but it would be difficult to find five consecutive inches of a brachial artery perfectly rigid, and the strength of a chain is its weakest link. Therefore I do not wish to dispute Dr. Sainsbury's contention on this point.

Dr. Leonard Hill's article is extremely interesting, but personally I do not see what it has to do with the fullness or otherwise of the brachial artery under the sphygmomanometer cuff. I am well aware that of recent years Dr. Hill's views on the capillary circulation have performed a complete *volte-face* from the time when he said that in the inverted body the pressure in the cerebral capillaries might amount to 100 mm. of mercury. He has for some years raised the capillary endothelium to the high level of a secretory structure, as Heidenhain had done before him. He has never succeeded in proving his own contention nor in abolishing the effects of capillary pressure. Even now he acknowledges that, "how living cells secrete into and absorb from the circumambient medium we do not know."

Every morning I douche out my nose with a saline solution; the secretion stimulated by the saline quickly stops, but when I lower my head six to twelve inches or more there is a rapid excretion of a limpid fluid rushing out in drops. I fail to account for this in any other way than the increase in capillary pressure which undoubtedly takes place.—I am, etc.,

Cannes, Feb. 25th. JAMES BARR.

THE INTRACUTANEOUS TUBERCULIN TEST.

SIR,—From the figures quoted by Professor Lyle Cummins on February 23rd (p. 336) the following conclusions might be drawn: (1) The vast majority of persons will react to 1/10 c.cm. of a 1 in 1,000 dilution, irrespective of whether they are tuberculous or not. (2) A lesser number will react to 1/10 c.cm. of a 1 in 5,000 or 1 in 10,000 dilution. On the whole, healthy persons are more likely to show this extreme degree of sensitivity than persons suffering from clinical tuberculosis, but a sufficiently large number of the latter group react to make the distinction valueless.

My own observations on the test are at present on a very small scale; but so far as they go they have been carried out carefully, and the results are more or less in harmony with those obtained by other observers with the same and with analogous tests. They are so strikingly at variance with those of Professor Cummins that I quote some of my results.

Results in 120 Cases (110 Adults) Tested with 1/10 c.cm. 1 in 1,000 T.A.F. Intradermally.

Group.	Cases.		
I. Pulmonary tuberculosis (sputum T.B.+)	25	15 pos.,	10 neg.
II. Non-pulmonary tuberculosis	7	7 ,,	0 ,,
III. Early tuberculosis (bacilli not found) ...	48	42 ,,	6 ,,
IV. Clinically free from tuberculosis ...	40	6 ,,	34 ,,
	120		

With regard to the cases in Group III, the diagnosis has not been confirmed by the demonstration of tubercle bacilli or by other evidence which would be regarded as unequivocal; Professor Cummins may reply that some of these cases should be included in Group IV. While I should not be prepared to admit this, I would point out that even the amalgamation of Groups III and IV would only give 55 per cent. positives against Professor Cummins's 93 per cent. among healthy persons (I am not sure how many persons would be considered to constitute 93 per cent. of a total of 46).

Moreover, I found that those clinically positive patients (Group I) who reacted were all patients with active disease in whom one felt that the prognosis was poor. My chronic patients who had returned from a beneficial course of sanatorium treatment, etc., were usually negative (and, incidentally, in some cases negative to 1/10 c.cm. 1 in 100). This observation also appears to be at variance with that of Professor Cummins; but it seems more in harmony with the fact that a person who has had a successful course of therapeutic tuberculin will give a negative reaction. If tuberculin tolerance confers any degree of tubercle-toxin tolerance the converse will likewise hold.

To my mind the most striking feature about Professor Lyle Cummins's work is the constantly high number of

positive reactions obtained in every test, irrespective of the type of person tested. My own conclusions may not be correct, but the comparative frequency with which I obtained negative reactions suggests that there may be some factor to explain the extraordinary discrepancy between his results and mine. I note that he employed old tuberculin; now old tuberculin contains glycerin, which is itself an irritant to sensitive skins; I invariably used T.A.F. (prepared by Meister Lucius), which is said to be free from glycerin and toxic albumoses. Moreover, there may be lack of agreement as to what constitutes a positive reaction. About twenty-four to thirty-six hours after testing a red flush may be seen at the site of inoculation; this does not, by itself, constitute a positive reaction. About the third or fourth day, in positive cases, a hard nodular swelling appears beneath the skin and is of maximum intensity about the sixth day. The redness may have disappeared by this time, but the nodule persists for fourteen days or more, and it is this nodule which is characteristic of a true positive reaction. It has been my practice to see patients a week after testing, and I do not regard a reaction as positive unless I can feel the nodule. I do not attach any significance to a mere redness appearing shortly after inoculation. These factors may to some extent explain the discrepancy between Professor Cummins's results and my own, but it seems unlikely that they can account for the whole difference. I fear that the truth is that the series tested is, in each case, too small to justify the drawing of definite conclusions. I would suggest, however, that a positive or negative reaction to tuberculin may be accounted for by one of many factors.

1. A negative reaction may be due to the fact that the person is uninfected.

2. A negative reaction may be due to anergy; this is seen in very advanced cases, and the diagnosis will be apparent without the employment of a tuberculin test.

3. A negative reaction may be due to high tolerance. This is seen (*a*) in persons who have had a successful course of therapeutic tuberculin; (*b*) in chronic tuberculous persons who have successfully fought the disease (that is, sanatorium treatment may produce a degree of tubercle-toxin tolerance which corresponds to tuberculin tolerance); (*c*) healthy persons who have developed high tolerance as a result of frequent "latent infections" which have been successfully resisted without the development of clinical tuberculosis.

4. A positive reaction indicates high sensitivity, and may be seen in a variety of phases. It always indicates "infection," and usually infection in an active state. It occurs in a high proportion of persons suffering from active disease, but who are not anergic; it appears in a high proportion of persons suffering from very early disease who have not yet developed tolerance; it develops at some time during the lifetime of a large number of healthy persons who have recently had "a dose of infection" and whose systems have not yet established a "state of equilibrium." A great many of these "healthy reactors" may never develop clinical tuberculosis, but it is impossible to predict this with certainty in an individual case.

(It will be understood that I am referring to reactions to test doses. All infected persons would react positively to a dose of tuberculin of sufficient potency.)

A fuller account of my observations will be found in the *Transactions of the Assurance Medical Society* for February, 1929, together with a review of the literature on the intracutaneous and other local tuberculin tests.

Professor Lyle Cummins remarks at the beginning of his article that an intradermal dose produces a local reaction and no appreciable general or focal response. Yet in his concluding paragraph he makes the surprising suggestion that this method should commend itself to those using tuberculin therapeutically.—I am, etc.,

SIR,—For more than thirty-eight years I have been studying the phenomena caused by hypodermic and even intravenous injections of tuberculin in every sort of chronic tuberculosis, and in the last few years I have been personally studying the effects of what I prefer to call intracutaneous or intracuticular (rather than intradermal) injections of tuberculin; at a low estimate I have made many more than 50,000 injections of all kinds. In all my early observations I carried out personally all the necessary laboratory and clinical work; I examined every sputum, and made all the bacteriological investigations upon mixed infections with my own hands.

I think that team work is not always trustworthy, and may easily lead to error, because correct observations, even upon the character of skin lesions, may require some special training and experience. Certainly, if assistants cannot be trusted to measure the doses of tuberculin for themselves, they are not likely to be versed in the technique of the administration of intracutaneous doses. Some knowledge of technique is necessary before one can rely on the effects of the intracutaneous injections of minute doses. I should not be inclined to draw conclusions from the results of intracutaneous injections of small doses of tuberculin given by a group of assistants. There are numbers of errors which may creep in *à la dérobée* at different stages of the proceedings. Accordingly I must ask medical men not to be impressed by the casual observations made by a few juniors and then summarized in statistical form. I am too jealous for the reputation of tuberculin to allow Professor Lyle Cummins's contribution (February 23rd, p. 336) to pass without a severe criticism of the "bricks and mortar" that form the basis of his statistical analysis. To appraise the merits or demerits of any new system one must be sure that the evidence comes from those who have had some considerable experience in this highly delicate field of inquiry.

Why Professor Cummins should select B. W. preparations in preference to the preparations known as Koch's T.A. and T.A.F., which are recognized all over the world as the standard of tuberculin of this type, he himself must explain. The choice of the testing reagent in such an investigation is of prime importance, and personally I should discount the value of experiments with this particular preparation.

If doses are reduced to 1 in 10,000 and 1 in 5,000 the borderline is reached when effects due to unskilled injection may be attributed to the innocent dose. I have confined myself to observations with 1 in 1,000 dilutions, and my conclusions are in entire disagreement with those of Professor Cummins. I should have imagined that the fact that healthy persons gave more severe reactions than the tuberculous would have aroused his critical faculty. Moreover, the only description of the reaction is one of linear measurement. I have never heard that reactions to tuberculin could be measured merely in centimetres.

Again, Professor Cummins's assistants were warned that diluted tuberculin is liable to deteriorate. My own experience is that this rapid deterioration is due to faulty technique—mainly contamination. I am well aware that Koch originally pointed out this fact, but I found out that strict technique removed this tendency.

Lastly, Professor Cummins is still obsessed with the phantasm of danger which Koch designated "thericht." I have used tuberculin openly at the Sydney University for ten years, and since then in London for another twenty years, and all my pupils would vindicate my view that tuberculin used by an expert in proper doses never does any harm. Yet Professor Cummins uses these words: "Special precautions were taken to avoid too deep a puncture. The escape of tuberculin into the subcutaneous areolar tissue vitiates the test and exposes the patient to the risk of a general reaction." Later, he says that in such attempts (the use of concentrations stronger than 1 in 500) "the possibility of dangerous constitutional reactions should not be lost sight of." In Professor Cummins's investigations the largest dose given intracutaneously is 0.0002 c.cm. After a long experience I am convinced that a single dose of 0.0002 c.cm. T.A. or T.A.F. given subcutaneously will never do harm. *A fortiori* it is

not possible to conceive that this dose, or even a much larger dose given intracutaneously, can do any harm.—I am, etc.,

W. CAMAC WILKINSON, M.D.Lond., F.R.C.P.

London, W.1, Feb. 27th.

COLLES'S FRACTURE.

SIR,—The two papers published in the *British Medical Journal* by Edwards and Clayton (January 12th, p. 61) and by Grasby and Trick (March 2nd, p. 391), are of great interest and importance. Neither, however, seems to me to explain the real cause of disablement in so many of these cases—namely, neglect to reduce the forward luxation of the lower end of the ulna so frequently present. When reduction of the fracture of the radius has been secured, the surgeon's thumb should be placed beneath the displaced lower end of the ulna and with a firm thrust it should be pushed dorsally. With this as a fixed point the hand and wrist are swung round into palmar flexion, pronation, and ulnar deviation. Dogma should be avoided in regard to the choice of splints and the position of fixation, but, in severe cases, the extreme Cotton-Loder position indicated above is the best, using moulded gutter splints of metal or plaster.—I am, etc.,

Edinburgh, March 2nd. W. A. COCHRANE.

IMMEDIATE ENUCLEATION FOR QUINSY.

SIR,—The kind remarks on the value of this method made by Mr. Whitelocke of Oxford (February 23rd, p. 374), following my memorandum of February 16th, will, I hope, be followed by others, both specialists and general practitioners, for the latter are the medical men who most often treat cases of quinsy from start to finish. Many specialists have told me that they enucleate an occasional case, and the journals of oto-rhino-laryngology often have abstracts of reports of foreign surgeons who praise the method. But English textbooks practically never even mention it as a possible course of action, whereas it should be regarded as the best course for over 95 per cent. of quinsies, just as immediate operation is regarded as the best treatment for the majority of cases of acute appendicitis.

Regarding Mr. Whitelocke's technique, it is what I learnt to do myself in 1914, but I could not get a decent snare until 1919; by that time I had found that the Collins pile forceps was superior to a snare, just as now most rhinologists use a Luc's forceps (not a snare) for ethmoid surgery, while a decent blunt-pointed, but sharp, straight (Mayo) scissors was superior to the knife. With the scissors the operation is so safe. Make a snip, wriggle the closed points into the extra-capsular space, then open the points widely, and the gloved finger does nearly all the rest. The lassitude and the pain make most quinsy patients prefer the ease of a "little whiff" over the side of their beds; the bother of "local" frightens them, and, personally, I have not wished to devitalize inflamed tissue with local anaesthesia, though, like Mr. Whitelocke, I always use it in debilitated patients—for example, during the course of phthisis or rheumatic fever. Since last August I have treated eight patients; six were between the ages of 18 and 25, and these needed the removal of *both* tonsils and the post-nasal adenoids, which the use of 10 or 15 c.cm. of ethyl chloride enabled me to do. Of the other two, one was too ill, and the other, a heavy, gouty publican, demanded to have as little done as possible, as he had to be at work next day, which he duly was!

I only removed the one tonsil, and nothing else, in these two cases, and hence novocain might have been useful.—I am, etc.,

Bishop's Stortford, Feb. 23rd. R. A. R. WALLACE, F.R.C.S.

SIR,—From time to time one reads in medical literature reports of cases the operative results of which are so excellent as to lead one to consider the necessity of altering one's technique. Such a case is that reported by Mr. Whitelocke in your issue of February 23rd (p. 374). His patient was suffering from "a large left quinsy" which must have been evolving for some time in view of its size and the attendant constitutional symptoms. Under the double influence of a sedative and local anaesthesia, the tonsil of the affected side was dissected out and the abscess evacuated. His patient made so rapid a recovery that on the following day he was correcting examination papers, and two days later he was conducting a viva voce examination.

My experience is so much at variance with that of Mr. Whitelocke, and his results are so incomparably better than my own, that I would ask him to be good enough to reply to the following questions.

1. What sedative (quality and quantity) does he give to overcome the trismus which has been such a distressing feature in so many of my cases? In many of them—even after local and general anaesthesia—the local inflammatory reaction has been so marked that I have had considerable difficulty in introducing a knife.

2. How does he, in such cases, differentiate—at operation—the capsule of the tonsil from the adjacent parts? In the few instances where I have tried to remove the tonsil in cases of peritonsillar abscess I have found it difficult to recognize the tonsil capsule and to deal with the haemorrhage which results.

3. What is his after-treatment of these cases? Although I try to be as gentle as possible, I cannot recall a case of even an uncomplicated tonsillar dissection where the patient would be capable of correcting an examination paper on the day following his operation.

—I am, etc.,

London, W.1, Feb. 24th. MICHAEL VLASTO.

THE DICK TEST IN SCARLET FEVER.

SIR,—With reference to the letter of Dr. William Brown on February 16th (p. 321), it would appear that he wishes us to believe that a positive Dick reaction in a patient who has had scarlet fever has a different significance from a positive Dick reaction in a person who has not had the disease. I cannot agree with this view.

The Dick reaction is a criterion of an individual's immunity to a specific toxaemia. The accepted conception of scarlet fever is that of a local infection with the *Streptococcus scarlatinae*, giving rise to a toxaemia which produces the typical rash (Kinloch, O'Brien, and others maintain that scarlet fever is only one phase of streptococcal infection). The Dick-positive reaction, whether in a healthy individual or a patient convalescent from the disease, always indicates susceptibility to scarlet fever.—I am, etc.,

Ilford, Feb. 25th. A. R. BALMAIN.

TREATMENT OF ACTINOMYCOSIS.

SIR,—In an interesting article on the treatment of actinomycosis with iodine (*Journal*, February 23rd, p. 347) Mr. Hubert Chitty quotes reports of two cases of mycetoma which had been cured by the same treatment. In Madras, where mycetoma (Madura foot) is a very common disease, we have for some years past persevered with the administration of iodine in many forms, including that recommended by Mr. Chitty, but without ever obtaining a cure of the disease. The main suffering in mycetoma is due to septic infection of the sinuses which are present, and which will improve with any sensible surgical treatment. The early effects of iodine and other drugs for this reason have sometimes been very promising, the late results always disappointing. At one time we hoped to cure the disease with deep *x*-ray therapy. The swelling was generally enormously reduced with this treatment, and the symptoms were alleviated, but after several months we were still able to cultivate the fungus from the tumour. A mycetoma, which does not become infected with other organisms, may, in my opinion, often remain small in size and cause very little suffering.—I am, etc.,

Chesières, Switzerland, Feb. 25th. E. W. C. BRADFIELD. Lieutenant-Colonel I.M.S.

CEREBRAL ANGIOSPASM.

SIR,—With reference to the correspondence on this subject in your issues of February 9th and 16th, it would appear that the condition is less uncommon than has been supposed. The following three cases may be cited.

A medical practitioner, aged 45 at the time, was on holiday, convalescent after paratyphoid fever, leading an unusually sedentary life, and smoking considerably more heavy tobacco than his customary quota; he had been constipated for a few days. While

at breakfast one morning he suddenly lost the power of his right hand and dropped his knife; on rising from his seat his right leg gave way under him and he fell. He was unable to speak, but did not lose consciousness, and was able to write with his unaffected hand. The condition lasted a few hours, and two days later he was perfectly well. There have been no recurrences nor other symptoms of vascular disease during the fifteen years which have elapsed, and he has been conducting a busy practice.

A male, aged 62, consulted me four months ago complaining of attacks of loss of power and dizziness. The attacks had commenced seven years previously, occurred periodically for two years, and then remained absent for five years; they had returned a few weeks before I saw him, and became more frequent, until he was having them as often as twice weekly. The attack commences with dizziness and loss of power on the left side, and unless he can support himself with the right arm he falls; there is no loss of consciousness or of the power to speak. After a period of ten to forty-five minutes he vomits and breaks out in a cold sweat, and the paralysis disappears; he feels weak and upset for the next two days, but no paralysis or weakness of the affected side persists. He was formerly a heavy drinker, but has given it up; he smokes two ounces of thick black tobacco per week; his bowels are constipated. On examination, three days after his last attack, no abnormality of any of the reflexes was elicited. The pulse was full and bounding, and of high tension; the arteries were thickened, but not calcareous; the heart was normal and the urine free from albumin. He improved during the next fortnight on purgative and general treatment, but three weeks later the urine contained albumin and a trace of blood. For the past two months he has had no attacks and the urine has been clear.

A male, aged 49, was referred to me by Dr. Ivy McKenzie complaining of symptoms of angina pectoris. The anginal attacks date from April, 1928. There is a clear history of attacks of cerebral angiospasm fully a year prior to the first attack of angina. In March, 1927, he awoke one morning with paralysis of the right arm and leg; the paralysis persisted for half an hour and then disappeared completely. There were two subsequent attacks, each lasting half an hour, and in each instance the paralysis disappeared completely after the lapse of that time. There have been no recurrences of these attacks since. On examination the nervous system was normal. The blood pressure was not raised, nor were the radial arteries palpably abnormal. The heart was of normal size, the sounds being of poor intensity, but free from murmurs; electro-cardiograms were suggestive of myocardial degenerative changes (inverted T in leads II and III and left ventricular extrasystoles). The urine contained no abnormal constituents. The patient's bowels were constipated and the tongue was furred.

In all three cases constipation appears to have been a factor; in two there is a history of smoking heavy tobacco. The association of the arterial spasm with arterio-sclerosis and chronic renal disease in one case, and with angina pectoris and probably disease of the coronary arteries in another, is interesting.—I am, etc.,

Glasgow, Feb. 24th. A. A. FITZGERALD PEEL.

SIR,—Mr. Juler's comment on March 2nd (p. 421) on the cases described by Dr. Gubb and myself is apposite. The diagnosis of my case at the time was not "cerebral angiospasm"; but whatever may be the pathological explanation, it probably applied also to Dr. Gubb's case. In my case the tentative explanation was that the resistance of the arteries was increased by senile change, and that with the low blood pressure attending dyspepsia the blood supply to the left hemisphere was insufficient to maintain its functions. It is an interesting question whether angiospasm was present. I have no recollection of the state of the kidneys; but the patient's general health was so good, and the paralysis so transient, that we may have had no occasion to examine the urine.—I am, etc.,

Cambridge, March 2nd. F. J. ALLEN.

SIR,—Mr. F. Juler, on March 2nd, objects, on the basis of ophthalmological evidence, to the theory of angiospasm put forward by Drs. Gubb and Allen. May I be allowed to side with them as the result of my own investigations, and bring some ophthalmological reasons for supporting this theory, which is usually termed "vascular crisis," a name given years ago by Pal in his monograph on this subject?

In advanced cases of hyperpiesis where the kidney efficiency is still good one can see a focus of exudation in the retina differing from retinitis albuminurica by its sharply outlined edges, its colour, and absence of ophthalmoscopically detected retinal oedema. It strikes the investigator by the fact that adjoining vessels are not covered by this exudation, and are seen sharply outlined, in contrast with retinitis albuminurica, where they are covered by the exudation; and their outline is diffuse. Such a focus may sometimes be accompanied by minute retinal haemorrhages—flat or striate—in its immediate neighbourhood. In one case I saw newly formed tiny vessels passing from the intact retina into the exudation, and abruptly ending near the periphery of the latter. This kind of exudation may lead to a permanent scar of the affected part of the retina, but it may also disappear after a few days, or even a few weeks, without leaving any trace; the retina completely recovers, as judged by the ophthalmoscope. The picture is especially beautiful in the red-free light.

In my opinion the most probable explanation of this phenomenon lies in the disturbance of local metabolism by diminished oxygen supply, caused by angiospasm of minutest arterioles or capillaries. That the larger vessels are not guilty is evidenced by the fact that only a very small part of the retina is affected, and that they do not show any change before, during, or after the appearance of such an exudation. If the angiospasm is extensive or has existed too long, or the lumen of the vessels is completely obstructed by atheroma or by a thrombus, a scar of the retina will result; but if the angiospasm is not so extreme, the retina may fully recover. Most probably a complete analogy exists between those retinal complications of hyperpiesis and vascular spasmodic attacks of cerebral origin.

The subject is too large to be covered in a letter, but I may add that additional evidence of vasomotor influence is afforded daily by using the oscillometer. An extreme case was published by Oertel, who saw actual gangrene of the intestine follow a prolonged spasm of the mesenteric artery. See also the theory of Volhardt on nephritis.

I cannot agree with the expression "arterio-sclerosis with hyperpiesia" in Mr. Juler's letter. The name is very misleading, and these diseases, in my opinion, have very little in common, if anything at all. I discussed this important matter more fully in my papers in the *British Journal of Ophthalmology* in 1927 and 1929.—I am, etc.,

London, E., March 3rd. N. PIRIE.

CARDIAC DISEASE IN SOUTH AFRICAN NON-EUROPEANS.

SIR,—It was with much interest that I read Dr. Heimann's paper on heart disease in South Africa (February 23rd, p. 344). Whilst in Kenya Colony I carried out a similar series of investigations amongst the natives there, and the statement of Dr. Carey Coombs (quoted by Dr. Heimann) prompted me to publish some of my observations.[1] It may be of interest briefly to contrast these with those of Dr. Heimann.

My observations were not confined to inmates of a hospital in a town, but were conducted partly at a hospital in a large native reserve and partly while on tour in the native reserves. In this way not only were large numbers of sick natives seen near their own homes, but systematic examination of healthy natives was also carried out. During my tour of over two years, approximately 1,800 in-patients were admitted to the hospital under my care, 12,000 labour recruits were examined (in the paper quoted above there was a printer's error in the figures), several hundred natives of all ages were examined in connexion with a census of the population and a systematic examination of normal blood pressures, and thousands of sick natives were seen on tour in the reserves. From all these I was only able to collect records of ten cases of valvular heart disease. It would seem, therefore, that this condition must be much rarer in East Africa than it is in South Africa. All these cases were aortic regurgitation, and I never encountered a case of mitral stenosis. The etiology is discussed in my paper, but my conclusions were *that certain* cases seemed most probably rheumatic in origin.

Syphilis is common amongst some tribes in East Africa, but in my experience syphilitic heart disease is rare. I am interested to note that Dr. Heimann had seen cases of syphilitic pericarditis, as I reported a case that appeared to be a gummatous pericarditis and myocarditis.[2] I

[1] *Kenya and East African Medical Journal*, September, 1928, p. [illegible]
[2] Ibid., May, 1928, p. 48.

blood pressure I never encountered, and arterial degenerations appeared to be of lesser degree than in Europeans. I also found that the normal blood pressure in the African native differed in certain respects from that in the European.[1]

In his conclusion Dr. Heimann remarks that there does not appear to be a wide divergence between the etiology, pathology, and clinical signs of heart disease in Europeans and African non-Europeans. With this I cannot altogether agree. As far as rheumatic, syphilitic, and other infective lesions are concerned, that remark appears to be true. But the type of disease that manifests itself as hyperpiesia, angina pectoris, and coronary thrombosis, and which presents such a serious menace to a healthy old age in the European, appears but rarely to affect the African.

I encountered a type of case in Kenya that I have not been able to correlate with any condition that I have seen described. The essential feature of these cases is a displacement of the apex beat to the left. On casual examination it appears that the heart is enlarged. The absence of any obvious reason for such enlargement led me to investigate a number of these cases.[2] I came to the conclusion, after such investigations as circumstances permitted, that the heart was displaced to the left, and not appreciably enlarged. There appeared to be no impairment of the function of the heart. There was no chest condition detectable that could account for this condition, but all the cases I encountered were associated with an enlarged spleen, and had come from malarious districts. I have been unable to decide whether the splenic enlargement could be responsible for cardiac displacement.—I am, etc.,

C. P. DONNISON, M.B., B.S.Lond.,
Late Medical Officer, East African Medical Service.

South Benfleet, Essex, Feb. 27th.

AMAUROTIC FAMILY IDIOCY.

SIR,—Dr. Robert Platt's further remarks on this subject on February 23rd (p. 373) are very acceptable. In regard to the R—— family tree, I have had news this week of a branch of it which has made South Africa its country of adoption.

Shalom R——, a son of the related ancestors, migrated there and married, his wife not being the remotest relation. They had two male children, of whom the younger, at the age of about 25, was confined in a mental institution. Full particulars of his case are not yet to hand. The elder had three children, by a wife who again was not in any way related to him, of whom the first was stillborn, the third is alive and well, and the intermediate one died. From the description of its symptoms it is reasonably certain that it was an amaurotic family idiot, though the condition was diagnosed at the time as "cerebral abscess."

A sister of Shalom R—— also lost a number of grandchildren in infancy from causes at present not ascertained.

This must only be regarded as an advance notice of these cases, since there has not yet been time to get into communication with the South African medical men concerned, as I hope to do. Further, the sensitive and apprehensive temperament of the adult members of the family may, they suggest, have some relationship with this disease. I offer it for what it is worth.

In this family, at least, I hold that heredity has a marked bearing, and I shall be much interested to know if Dr. Mandel, on deeper investigation, can establish collaterals to his cases.

Assuming that all these cases are the outcome of DR—DR marriages, it would appear that DR types are not rare throughout the scattered Jewish race, in which event this disease should be more common, or that the DR members of this family tree have been highly unfortunate in selecting their mates, even from widely separated parts of the world. Alternatively, I suggest that in the R—— family there is a tendency to this disease more strong than a simple Mendelian recessive characteristic.

While Mendel propounded a working hypothesis of the first order, he left confessedly unexplained the origin of the transmissible character of a "sport," to which category this disadvantageous condition may belong. In sporadic cases we may imagine that transmissible virulence has not been attained, especially as the subject has no chance of breeding. Mendelism, satisfactory up to a point, awaits its Einstein.—I am, etc.,

D. STENHOUSE STEWART.

Hull, Feb. 23rd.

INTRACRANIAL SURGERY.

SIR,—In the review of my report to the Medical Research Council on intracranial surgery, published in your issue of March 2nd (p. 406), you "express regret at the almost complete omission of the names of English neurological surgeons" from the bibliography. May I point out that the report was not concerned with the work of English neurological surgeons, but was, to quote from its opening paragraph, "an attempt to describe the methods of diagnosis and treatment employed in Dr. Harvey Cushing's clinic at the Peter Bent Brigham Hospital, Boston"?

It should also be explained, as was done in the report, that the neuro-surgical clinic is merely one part of the general surgical clinic, directed by Dr. Cushing. The neuro-surgical cases are not segregated, but are scattered through the general surgical wards so that all house officers and surgical dressers may come into contact with them.—I am, etc.,

HUGH CAIRNS.

London, E.1, March 5th.

*** We are very glad to publish Mr. Cairns's letter, which corrects a misapprehension. His list of references applies directly to the text of the report, and is not a general bibliography.

THE CAUSE AND CURE OF MORNING SICKNESS.

SIR,—Dr. Richmond, in his instructive memorandum in the *Journal* of February 23rd (p. 349), suggests that the cures he has wrought in the condition of the morning sickness of pregnancy have been due to opening the cervical canal by means of tampons of glycerin.

In view of the recognized propensities of glycerin, when locally applied, of acting as a stimulant to uterine activity resulting in the evacuation of the viscus, it would be interesting to know whether in any of the cases so treated the cure of the pathological condition coincided with a premature termination of the physiological one.—I am, etc.,

JAMES KILPATRICK REID, M.B., Ch.B.

Birkenhead, Feb. 25th.

ACTINOTHERAPY AND DEAFNESS.

SIR,—I wish to thank Mr. Norman Barnett for his suggestion (February 16th, p. 323) of a functional cause of the case of chronic deafness which I reported in your columns on January 19th (p. 133). When I recorded the case I gave all the information I could vouch for. Since writing, a specialist's report has been placed in my hands, dated December 10th, 1926, from which I quote, "Her deafness is apparently of some considerable standing, as the middle ear contents, ossicles, foot piece of stapes, show marked adhesions—fixation."—I am, etc.,

T. C. HUNTER.

Morpeth, Feb. 25th.

Universities and Colleges.

UNIVERSITY OF OXFORD.

IN Convocation on February 26th a decree was passed to discontinue the examinations for the Diploma in Public Health until further notice.

On the motion of Dr. E. W. Ainley-Walker, a decree was passed unanimously accepting with gratitude the gift of £1,000 from the fund placed at the disposal of the Prime Minister by Lord Beaverbrook for the promotion of medical knowledge. This sum, it was announced, will be used for the establishment of studentships for medical research.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 1st the following medical degrees were conferred:

M.B., B.Chir.—J. A. Hartley, J. D. Proctor.
M.B.—A. J. Dix-Perkin.

UNIVERSITY OF ABERDEEN.

THE Senatus of the University of Aberdeen has resolved to confer the honorary degree of LL.D. upon Dr. Walter Elliot, M.P., Parliamentary Under-Secretary of State for Scotland. The graduation ceremony will be held on March 27th.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

The Local Government Bill in the House of Lords.

Discussion in Committee.

IN the House of Lords on Tuesday, March 5th, the Local Government Bill was considered in committee, the EARL OF DONOUGHMORE in the chair.

The MARQUESS OF READING moved an amendment to Clause 4 (provisions as to the alternative powers of giving assistance), providing that in so far as administrative schemes prepared by local authorities under the clause related to hospitals they should take reasonable steps to seek full co-operation with every voluntary hospital in the area of the authority.

Lord DAWSON OF PENN also had an amendment on the order paper, to the effect that a council in preparing a scheme under this section shall have regard to the desirability of consulting (*a*) any body existing in the area which is so constituted as to be representative of the voluntary hospitals in the area, and (*b*) any body existing in the area which is so constituted as to be representative of the duly qualified medical practitioners in the area, including those on the medical and surgical staffs of any voluntary hospitals in the area.

The EARL OF ONSLOW, speaking on behalf of the Ministry of Health, intimated that he would be prepared to move a new clause to the following effect: "The council of every county and county borough shall make such arrangements as they think desirable for securing that the functions transferred to them under this part of the Act with respect to the provision of hospital accommodation will be discharged after consultation with such body, if any, within the county or county borough as they consider to represent the voluntary hospitals in the area."

This new clause was criticized in the subsequent debate by several lords as too loosely drafted and vague in its terms, and complaint was made that it did not meet the desire expressed by Lord Dawson to ensure consultation with the medical profession in each area.

Lord ONSLOW said that the Government desired to meet the wishes of the House. He undertook to have the clause redrafted before the report stage. He hoped that in its new form it would be acceptable to the House, including Lord Dawson.

The MARQUESS OF READING withdrew his amendment.

Lord DAWSON said he would not move his amendment, but he hoped that they would get something more out of the Government.

Debate on Second Reading.

In the House of Lords, on February 26th, the second reading of the Local Government Bill was moved by the LORD CHANCELLOR (*Lord Hailsham*), who, in his exposition of it, said that under the bill, by centralization and specialization in selected institutions under the Poor Law, a far more skilled service could be provided than was possible to-day. The bill gave power to the county councils for provision of hospitals or maternity homes or for the making of subscriptions and donations to existing hospitals and institutions. Provision was made for the recovery from those who accepted assistance in these public institutions of a contribution towards the expense, but that did not apply to treatment in infectious hospitals, including hospitals for the treatment of tuberculosis and venereal disease, since it was in the interests of the public that persons should be isolated in those institutions as soon as possible. Provision was also made for acceleration of the process under which medical officers of health became full-time servants of the State, and for the making of regulations prescribing the qualifications of such officers and of health visitors. The bill further enjoined a survey by county councils of the existing accommodation in hospitals for infectious diseases.

Lord PARMOOR moved the rejection of the bill.

The debate was resumed on February 27th. Lord BEAUCHAMP contended that the bill should have split Poor Law functions into three, all the health, mental deficiency, and children's services being given to the county councils.

Lord DAWSON OF PENN said he proposed to limit his remarks to the parts of the bill of which he had some knowledge, and particularly that which concerned the foundation of hospitals, a subject concerning which discussion in the House of Commons had been strictly limited. In Part I of the bill were clauses which enabled and might encourage councils to found general hospitals for treatment of general medical and surgical disease. This new departure probably ushered in a new era for medicine in this country. He thought the proposals right if suitably safeguarded, but neither county councils, county borough councils, nor their medical advisers had previous experience of the whole field of curative medicine. They had a limited knowledge in the application of curative medicine at tuberculosis clinics and in maternity; the fact that the councils had run Poor Law hospitals was but little training for the running of big general hospitals. The powers in the bill enabled the councils to convert Poor Law hospitals into general hospitals and to found general hospitals at a time when the demand for hospital accommodation was increasing throughout the country. Hospitals were now needed for the whole nation. They used to be for the sick poor; now everyone was poor, and sometimes sick. Social and economic conditions and the progress of knowledge demanded hospitals. The art of medicine now called to its aid a number of sciences, and these new sciences required team work. Years ago a disease of the chest required a stethoscope and a bottle of medicine. To-day it also required, besides the clinical skill of the physician, the radiologist and the bacteriologist. A surgeon who wished to operate on the stomach now perhaps required the skill of the chemist or of the radiologist. Many branches of knowledge had to act in co-ordination. Each of these specialties required its equipment, and the equipments had to be brought together for efficiency and for cost, because the more science progressed the greater the cost of treatment. But for what he might call mass production a large proportion of the population would be without these benefits—another reason why people in increasing numbers needed hospital treatment. He admitted that the voluntary hospitals of the country could not entirely fulfil these needs, and believed that one of the questions before the Government when preparing the bill was how this hiatus could be filled up. There could be a considerable extension of a form of co-operative hospital in garden suburbs and garden cities, where there was great scope for a system of co-operative treatment. Co-operative health societies could be linked with insurance societies to solve some of the difficulties of hospital provision, but even when that had been done a large gap would remain to be filled. All the conditions of to-day tended to move the location of illness from the home to the institution, and so the need for hospital accommodation was great. Yet, as he had said, neither the councils nor the medical staffs had experience in the curative treatment of disease. The councils were advised by medical officers of health and by people who looked after clinics. In their own domain these did excellent work, but their experience of curative medicine was little or none, although four-fifths of the medical men in this country were engaged in it. Part I of the bill lacked appreciation of the essential conditions of success. In effect, it said to the Public Assistance Committees, "You can convert your Poor Law hospital, if you wish. You can build large hospitals. We would like you to co-opt a few people who know something about the running of a general hospital, but we will not force you to do so." A hospital was not a building made with hands. It was an organization, an assemblage of great traditions. The efficiency, the flexibility of administration, the public spirit, and the warmth of heart of the hospital service of this country had all grown up round the voluntary system, which had made the hospitals of England famous throughout the world. The ambition of the young man of talent was to get to these hospitals. There he worked for years at a pittance to gain experience, reputation, and discipline. That was the recognized road within the profession, and from the hospitals also the nurses came. Obviously the voluntary hospitals should be the kernel round which any new hospital system should be built, and legislation should provide that this mode of progress was not only permitted but secured. The voluntary hospital was a tender plant, and could be easily killed. Let it direct in forming up the new hospital policy which was needed for the country. Supposing there were no co-opted minority on the Public Assistance Committees, and that they had a free hand. Supposing—and this was not imagination—that a council were returned committed to the policy of a whole-time municipal medical service. That council would build up a service independent of the voluntary hospitals, competing with them, and overlapping them. At the moment some boroughs were trying to run a medical service. The avowed object of certain people was to set up municipal hospitals, staff them with a full-time staff, and run them as a municipal service. That would be a disaster. How would they get their staff? Presumably they would advertise for it, as if physicians and surgeons grew like gooseberries on a bush. Advertisements did not bring in the right people, and already there had been lamentable consequences of the wrong people staffing hospitals. The Government should make compulsory the co-option of a minority skilled in hospital work on the Public Assistance Committees. On Education Committees it was compulsory to have a co-opted minority of people skilled in education. If that was sound for education, why not do it for health? The medical profession had practically unanimously asked that co-option of a minority skilled in hospital work should be compulsory. The King Edward's Hospital Fund had taken the same line. Could the House of Lords desire to start a new venture which would lead to a wide establishment of municipal hospitals and neglect all the traditions and knowledge that had gathered during the years? He wished to urge one other amendment on

Government. Hitherto the health services of the country had been run by men who had specialized in preventive medicine—medical officers of health, tuberculosis officers, school medical officers. He admired their work, but they had never had anything to do with disease, and many of them had not been in contact with hospitals since their student days. How could they be expected to advise their councils wisely on curative hospitals? Ever since the Ministry of Health Bill passed the policy of the official doctor had proceeded on lines divergent from those doctors, constituting four-fifths of the profession, who belonged to the curative branch. That divergence was lamentable, and would be still more serious if it continued. To meet it he suggested that there should be set up, under the chairmanship of the medical officer of health, in each district which the council administered, an advisory council of doctors. This proposal had been before the Ministry of Health for some time, and would bring to the aid of the men who had to administer the experience of the men who knew. He believed the hospital policy of the bill could confer great and continued benefit on the community if the Government would accept the safeguards he had suggested in the form of amendments at a later stage.

Lord UNSLOW, replying for the Government, said Lord Dawson of Penn had ably dealt with the question of hospitals. On this matter there was some misapprehension about the effect the bill would have. The bill only made one change in the law—by giving county councils the powers now possessed by county boroughs and county districts to establish hospitals or to subscribe to existing voluntary hospitals. Those powers were given under Section 131 of the Act of 1875 to local authorities; but in those days local authorities did not include county councils, because these did not exist. The bill, therefore, merely put county councils in the same position as county boroughs. It gave county councils the right and duty to take over existing Poor Law institutions. They would allocate these to the best advantage, using one for tuberculosis, another for chronic cases, and so forth. As to voluntary hospitals existing, or to be established in the future, the Government looked for the closest co-operation between them and local authorities. The county councils, with their new hospital activities and powers, should work in close co-operation with voluntary hospitals in London and everywhere else. Such co-operation had been growing fast lately, and they hoped the bill would increase it. It would be difficult to amend the bill in order to make a statutory provision on this question. Possibly the machinery of the Voluntary Hospitals Committee, which included representatives of the hospitals, the medical men in the district, and the local authorities, might be utilized. Lord Dawson's proposal for compulsory co-option could be more easily discussed if he later moved an amendment. Turning to the question of block grants, Lord Onslow said it had been contended that this system, especially in the case of maternity and child welfare, would militate against the efficiency of the services. Maternity and child welfare services were most essential in the poorer districts, which, under the percentage grant, could not spend a considerable amount upon them. Under the bill necessitous areas would receive a large proportion of the Exchequer contribution, and so would be able to devote more money than in the past to maternity, child welfare, and other health services. Against local authorities which did not spend sufficient money on maternity and child welfare, the Minister would have under the bill a weapon which had never existed before.

The House divided and read the bill a second time, by 102 to 20.

The House of Commons was again in committee on the Local Government (Scotland) Bill on March 5th.

Army Estimates.

Presenting the Army Estimates to the House of Commons on February 28th, on the motion that the Speaker leave the chair, Sir LAMING WORTHINGTON-EVANS drew special attention to the assistance given to the army by members of the medical profession. He said the army could derive nothing but benefit from a good understanding between the civil and military branches of the medical profession, which displayed itself in fruitful co-operation on many committees. He hoped that as the scope and attractiveness of the Army Medical Service became better known through their advocacy the present welcome increase in the number of candidates would continue.

Mr. J. W. LAWSON commented on the recruiting statistics in the Army Report. Dental standards had been lowered, the height standard had been lowered from 5 ft. 3 in. to 5 ft. 2 in., yet only 36 per cent. of recruits were accepted.

Lady IVEAGH protested against the test-firing of 16 in. shells from Kent to a target in Essex, passing over the town of Southend. This affected the value of that town as a resort for convalescents. She had a protest against the firing, which had been signed by thirty-four medical men practising in Southend. This letter declared that "instances in which definite injury has resulted to our patients are within our experience, while ill effects on children have been frequently brought to our notice." Mr. DUFF COOPER said the War Office were alive to the hardships of her constituents in Southend, but had not been able to discover a more suitable place for this firing.

Mr. BECKETT spoke of the small proportion of cases of tuberculosis in the army which were admitted to be attributable to service. The Admiralty had agreed that such men should have the right of independent appeal and adjudication. The Secretary for War should also do justice to these cases.

A vote for War Office pensions and other non-effective charges was taken later the same night. Dr. VERNON DAVIES asked whether there was any chance for a service man to appeal against the decision of the medical chiefs of the War Office or of the authorities at Chelsea. Were there any methods by which a man could obtain, either himself or through his agents, any record of his medical history or of the reason which determined whether he was entitled to a pension or not? Medical men were being constantly worried about such cases, and, as far as Dr. Davies could find out, the opinion of a civilian medical man in a case of that kind was of no account. He did not criticize the authority or the skill of the medical officers of the War Office or at Chelsea, but it would give satisfaction to the civilian medical profession to have information of the procedure in this class of case.

Sir LAMING WORTHINGTON-EVANS said that when a man claimed a pension on account of disability his papers went to the board at Chelsea, and were examined with the greatest care. The medical evidence was sifted, and the man was examined. The man had an appeal to the medical authorities at the War Office, and the board there really did give justice in these cases.

Dr. DAVIES thanked Sir Laming for his explanation, but asked him to consider the possibility of co-opting civilian members to the appeal board at the War Office.

The House agreed with the vote. Closing the debate, Mr. DUFF COOPER said the health of the troops at Shanghai had considerably improved, but was not satisfactory.

Bills.

On February 28th the House of Lords passed the Factory and Workshop (Cotton Cloth Factories) Bill through committee. This bill authorizes the issue of regulations regarding humidity in cotton-weaving sheds. On the same day the House of Lords further debated legal points in the Age of Marriage Bill.

Illicit Drug Trade in China.

On February 27th, in a reply to Sir Robert Thomas, Mr. G. LOCKER-LAMPSON said that, with a view to preventing participation by British subjects in the illicit drug trade in China, the British Government had enacted regulations under which subjects so offending would be liable to heavy penalties, and in the last resort to deportation.

On February 28th Mr. CECIL WILSON asked the Home Secretary to explain what had become of a balance of 1,017 kilograms of heroin, unaccounted for in the totals of that drug exported from, or available for, internal consumption in the United Kingdom in 1924 and 1925. Sir W. JOYNSON-HICKS replied that the figures included 745 kilograms of heroin in 1924 and 15 kilograms in 1925 which were not necessary as such, but were reconverted into morphine. The bulk so reconverted consisted of illicit consignments to the Far East, which were seized at Hong-Kong and sent home to this country for disposal. The balance in each year approximated to the general average of the surplus of heroin imported and manufactured over that exported or re-exported. The substance was useful for medicinal purposes, and the object of the Home Office was to prohibit its use except properly in medicine. Heroin seized at Hong-Kong was not destroyed, but sent here to be utilized for medicinal purposes.

Sterilization of Mental Defectives.—Colonel WEDGEWOOD asked, on February 27th, whether the Minister of Health had received a petition, signed by many doctors, asking for the sterilization of criminals and mental defectives, and whether the Government intended to take any action in the matter. Mr. CHAMBERLAIN replied that he had received a resolution urging that an inquiry should be held into the best methods for dealing with mental deficiency, including a special inquiry into the possibility and advisability of legalizing sterilization under proper safeguards and in certain cases. He could not yet indicate the intentions of the Government in the matter.

Inmates of Mental Institutions in Scotland.—Sir JOHN GILMOUR stated, on March 5th, that in Scotland, at January 1st, 1929, there were in royal asylums 3,616 lunatics; in district asylums 12,515; in parochial asylums 241; in private asylums 42; in the lunatic wards of poor-houses 830; and under care in private dwellings, including specially licensed houses, 1,623; making in all a total of 18,917. There were, in addition, 969 patients voluntarily in residence in the respective institutions at that date, and 73 inmates of the criminal lunatic department of the prison at Perth.

Hookworm Disease.—Mr. AMERY told Sir Robert Thomas, on February 25th, that the medical departments of the East African dependencies were alive to the importance of combating hookworm disease. Special intensive campaigns against it have been undertaken in the past two years by the medical departments of

Kenya and the Tanganyika Territory with encouraging results, and were still in progress. No returns of the number of cases successfully treated in 1928 were available. While officers are from time to time deputed to undertake special work against the disease, its treatment was part of the ordinary duties of all Government medical officers in the East African dependencies.

Fibrosis of the Lungs.—Sir W. JOYNSON-HICKS stated, on February 28th, that he had seen the report by a medical inspector who attended an inquest at Leeds on a woman who, up to four years ago, was employed at an asbestos factory in Armley, and who died of fibrosis of the lungs. Sir William said it appeared from medical evidence that death was due to the effects of dust. The effects of this dust were already the subject of a comprehensive inquiry by the medical inspectors, one of the main objects of which inquiry was to determine the precautions needed for the prevention of this disease.

Early Rickets in Distressed Areas.—In answer to a question by Dr. Vernon Davies, on February 25th, Sir KINGSLEY WOOD stated that the measures taken to prevent the onset of rickets, and to deal with such cases as arose, were a matter in the first instance for the maternity and child welfare authorities of these areas. Mr. Chamberlain was advised that the authorities were alive to this matter. He had recently sanctioned increased expenditure on the supply of milk to expectant and nursing mothers and to young children in these areas. Dr. DAVIES asked whether Sir Kingsley would communicate with the South Wales health authorities to see that cases of rickets were followed up after treatment. Sir KINGSLEY WOOD said that he would look into that. Dr. DAVIES asked Sir Kingsley if he knew this was not a question of shortage of food, but of improper food which the children were receiving. Sir KINGSLEY WOOD said that was so. He reminded the House that the report just issued by officers of the Ministry of Health stated that to a great extent disease has been controlled by means of maternity and child welfare services.

Maternity and Child Welfare Centres in Scotland.—The LORD ADVOCATE (Mr. W. Watson) told Mr. Campbell Stephen, on February 26th, that at the end of 1928 there were 193 maternity and child welfare centres in operation in Scotland. During the year ended December 31st, 1927, the number of mothers who attended the centres for advice or treatment or for food and milk was approximately 55,000. The applications for food and milk were 17,208 in respect of mothers, and 44,598 in respect of children. The total expenditure on food and milk for the year ended May 15th, 1928, was £52,864, and the total expenditure under schemes of maternity service and child welfare, excluding food and milk and administrative expenses, was £205,931.

Consumption of Opium in Hong-Kong.—Asked by Mr. Ponsonby to give the reasons for the failure to restrict the consumption of opium at Hong-Kong, Mr. AMERY said the Hong-Kong Government had established a monopoly of the sale of opium with the intention of restricting consumption by charging high prices. That monopoly was not effective because of the abundance of cheap opium in China and the proximity of Chinese territory. In the hope of solving the difficult problem in Hong-Kong the British Government suggested in 1928 that the League of Nations should send a commission of inquiry to investigate the opium problem in the Far East. The League had agreed to do so.

Radium.—Mr. LOCKER-LAMPSON stated, on February 27th, that in a few weeks' time the Government would receive a report from a subcommittee of the Committee of Civil Research on the radium requirements of this country and the possible sources of supply. Until this report had been considered the Government could not judge whether to ask the League of Nations to institute an inquiry into the conditions of production and sale of this substance. On the same day Mr. CHAMBERLAIN, in reply to Dr. Little, said that the Medical Research Council, in apportioning the stock of radium salt which had been bought at the public expense, paid consideration to the technical experience in its use of those to whom it was supplied.

Registration of Doctors for Military Purposes.—Mr. MALONE asked the Secretary for War, on February 26th, whether circular letters were being addressed by district military headquarters to medical practitioners in the district requesting the practitioners to fill in a form stating whether, in the event of mobilization, they would be willing to devote a portion of their time to work in the local military hospitals in order to fill the vacancies created by the withdrawal of regular Royal Army Medical Corps officers for the expeditionary force; whether this registration of doctors for military purposes was being carried out all over the country on his instructions; and, if so, with what object. Sir LAMING WORTHINGTON-EVANS answered that inquiries were being made by the military authorities in various parts of the country to see how far the local civil medical practitioners could be counted on in the event of mobilization to act in a civil capacity in hospitals in the United Kingdom in place of Royal Army Medical Corps officers until relieved by other Royal Army Medical Corps officers.

Medical History of Discharged Soldiers.—On February 28th Mr. SHEPHERD asked a question about the medical history of a man discharged from the army. Mr. DUFF COOPER, Financial Secretary to the War Office, said the medical records of soldiers were confidential. To disclose details from them would be contrary to established practice. Dr. VERNON DAVIES asked whether an appeal was not handicapped if the appellant could not get particulars of the medical history of the case. Mr. DUFF COOPER said the previous history was open to the people advising the appellant.

Health of the Mercantile Marine.—Sir RICHARD LUCE asked, on February 28th, whether the necessary sickness and mortality statistics were available or in preparation for the joint committee appointed by the Board of Trade and the Ministry of Health to consider matters affecting the health of the mercantile marine. Commodore KING replied that in addition to statistics published by the Registrar-General an annual return was published by the Board of Trade of all deaths on ships registered in the United Kingdom. Whether these statistics could be improved or supplemented was being considered by the joint advisory committee.

Colonial Surgical Appointments.—Dr. DRUMMOND SHIELS asked Mr. Amery, on February 25th, whether in one colony certain surgical appointments were reserved for holders of the Fellowship of a particular Royal College of Surgeons; whether this practice had the approval of the Colonial Office; and, if not, whether he would call the attention of the Colonial Government to the matter. Mr. AMERY said he was informed that in one of the colonies there was a departmental regulation that had the effect of excluding from consideration for certain surgical appointments candidates other than holders of a particular surgical diploma. He did not think that assignment to particular technical posts could fairly be based on academic qualifications alone to the exclusion of other qualifications, such as experience, skill, and personal suitability. He was inviting the Colonial Government concerned to attend to the matter.

Factory Inspectorate.—Answering Mr. Kelly, on February 28th, Sir W. JOYNSON-HICKS said the number of factory inspectors actually employed was now slightly larger than six months ago, vacancies having been filled. The question of increasing the factory inspectorate was being considered by a departmental committee under the chairmanship of Sir Vivian Henderson. The House would be informed of the recommendations of this committee.

Notes in Brief.

There are in England ninety-eight day nurseries recognized by the Ministry of Health. The policy of the department is to encourage these nurseries.

On the allegation that bombs or shells carrying disease or plague germs were used by the German forces on the Western Front during the war the British War Office has no information beyond that contained in the official history of the war.

Obituary.

SIR HECTOR MACKENZIE, M.D., F.R.C.P.,

Consulting Physician to St. Thomas's Hospital, the Brompton Hospital for Consumption, and King Edward VII Sanatorium.

WE deeply regret to announce the death on Saturday, March 2nd, at his residence in Upper Brook Street, of Sir Hector William Gavin Mackenzie, at the age of 72. He was ill for a few days only with symptoms of bronchopneumonia of the type which is now so prevalent.

Hector Mackenzie gave evidence of his outstanding ability at an early stage of his career, and such were the opinions formed of his prospects at Cambridge that it was regarded almost as a ground for condolence when he graduated in 1880 as fifth Wrangler. Immediately after this he was elected a Fellow of his own college, Emmanuel. In 1882 he entered the medical school at St. Thomas's Hospital and carried off various prizes, the culminating one being the Mead Medal for Clinical Medicine. He qualified in 1884 as M.R.C.S.Eng., and graduated M.D. Camb. in 1888. After holding the junior medical appointments at St. Thomas's, he was elected assistant physician, then physician, and ultimately, on his retirement in 1919, consulting physician. Concurrently with these appointments at St. Thomas's he was the holder of similar posts at the Brompton Consumption Hospital, and for a shorter time at the Royal Free Hospital. He became Fellow of the Royal College of Physicians in 1892, examined in medicine for the Conjoint Board for four years, served as censor for three years from 1916, and delivered both the Bradshaw and Lumleian Lectures. During the war he served as captain in the R.A.M.C.(T.) attached to the 2nd London General Hospital at Chelsea. He was knighted in 1923.

Without any doubt Mackenzie was a most able general physician, and extended his purview over the whole range of medicine. But in two directions he could claim to be a specialist of the best type. He spoke with authority on diseases of the thyroid, for in 1892, simultaneously with, but independently of, Dr. Fox of Plymouth, he discovered the epoch-making fact that thyroid extract was as effective when given by the mouth as under the skin. The authority with which he could claim to speak on the subject of diseases of the chest was perhaps based rather on his long association with Brompton Hospital and the King's Sanatorium than upon any achievement parallel to that in the territory of the ductless glands, but it was fully

justified by virtue of his highly developed skill and ripe experience. Mackenzie's writings were mainly devoted to the two lines of thought to which reference has just been made. He was not the author of any independent treatise, and his literary work has to be sought either in the reprints of lectures or in articles in various systems of medicine. He wrote well and with restraint; it might perhaps have been lighter reading if there had been less of the latter quality. His characteristics as a physician and teacher may be deduced from the sketch of his personality which it is the aim of the following lines to give. They are written, as might be supposed, by a colleague and close friend of many years' standing.

"There was a curious dichotomy between Mackenzie the hospital physician and Mackenzie the social individual; this was definite enough to justify their being tabulated under (*a*) and (*b*). It was not, of course, a case of Jekyll and Hyde, for they were both Jekylls, but of a different type. Jekyll (*a*) was an extremely taciturn individual. There was no dourness about the taciturnity, which seemed to depend upon an abnormally high threshold for speech. He never went to meetings of his colleagues, and on his clinical ward rounds it was not altogether easy for the students to extract the spoken word. This was always good when it came, but the difficulty was to get it. In spite of this difficulty of communication Mackenzie's students got to love him, and the friendships thus formed proved in some cases to be lifelong. In his relations to hospital patients Mackenzie suffered to some extent from his difficulty in establishing a personal tie, but at all events they had from him the best that modern medicine could give. Mackenzie as a social entity—whom we may call Jekyll (*b*)—was a different being. He was quiet still, but full of humour, and possessed of a characteristic laugh which was rather a chuckle than a laugh. He was a cultivated musician, was a good linguist, and a reader of wide scope. In congenial society, preferably one of both sexes, he could let himself go, and was worthily described as 'the life and soul of the party.' His great hobby was skating, and he was enjoying this within a fortnight of his fatal illness. This is a very faulty sketch of what was a most complex character. No attempt has been made to conceal the existence of a negative phase beyond which many colleagues and potential friends found it difficult to penetrate. If they had succeeded they would have found a being of remarkable charm and of singularly rich equipment."

Sir Hector Mackenzie, when Bradshaw Lecturer before the Royal College of Physicians of London in 1916, chose as his subject exophthalmic goitre; and in 1922 his Lumleian Lectures were devoted to diseases of the thyroid gland. He also contributed articles on the thyroid to Allbutt's *System of Medicine*. In 1902, when the British Medical Association last met at Manchester, he was president of the Section of Pharmacology. He married in 1890, but leaves no children.

Mr. W. H. BATTLE, consulting surgeon to St. Thomas's Hospital, writes:

As one who was closely associated with Hector Mackenzie during the greater part of forty years, I should like to add a few lines to those which have been contributed by others of his colleagues and friends. He was a difficult man to know, and did not encourage attempts to become intimate; but when one did have the privilege of intimacy he was responsive and revealed a very fine character. He was never too busy, even at the end of a long round in the wards, to see another hospital patient, and never allowed himself to be hurried. His attitude was one of quiet confidence, which impressed the patient, as well as others present, conveyed a feeling that he recognized the importance of what he was told, had weighed the evidence, and that the verdict was fully considered before it was given. It sometimes appeared to patients that "the Doctor" had not told them everything that they wanted to know, but as time passed they found that they had been told the essential facts. Whilst he was rightly regarded as possessing a special knowledge of diseases of the chest, his insight in a difficult case often proved a surprise to those who did not understand his modest demeanour, or know the extent of his knowledge of medicine. His contributions to the study and treatment of diseases dependent on changes in the thyroid gland were especially valuable. A consistently hard worker, he did not allow himself much in the way of holiday or recreation. In recent months he appeared to be somewhat failing in health, but he always scoffed at the suggestion that he should take care of himself, and did not deviate from the path of duty which he had marked out as the one to follow. It will be evident that his opinion would be extremely valuable in difficult insurance cases, and it will be hard to follow a man who was so practical and conscientious in even minute details, one of such high ideals, wisdom, and forgetfulness of self.

Dr. FRANK C. EVE, consulting physician, Hull Royal Infirmary, writes:

We have lost Sir Hector Mackenzie, and no one can fill the gap; we can but treasure his memory. I knew him for thirty years—as his clerk, house-physician—and ever afterwards sought the fruits of his wisdom. He was always the same—quiet, unassuming, equable, and kindly through and through, with dry humour twinkling in the background. He had a remarkable mind, like a complicated and rather ponderous machine of which the workings were entirely hidden. You presented your problem to the machine, and after a while began to wonder if anything was going to come out. Eventually—perhaps extracted by questionings—the solution was duly delivered, thoroughly thought out, and often highly illuminated. He had the great gift of sagacity, which is so much rarer than cleverness. Once I joked with him about the German language being the only one to possess a special word (schadenfreude) to denote "joy at the misfortunes of others." The conception seemed genuinely to pain and shock him—revealing his gentle nature. He brought the best side out of those who knew him, partly by his essential goodness and partly because he seemed only to see one's good points and to be blind to one's faults. This rare quality will yield him many mourners. Of this great and simple physician the words might have been written, "Write your name with love, mercy, and kindness in the hearts of those about you, and you will never be forgotten."

We have to record, with regret, the death of Sir JAMES HOSKER, which took place at his home in Bournemouth on February 13th. James Hosker, who was born in 1857, received his medical education at the London Hospital, qualifying M.R.C.S., L.R.C.P. in 1882. After holding various posts he engaged in general practice in Boscombe, holding in turn appointments of surgeon and of consulting surgeon to the Royal Victoria and West Hants Hospital. Hosker took an active part in public life. He was chairman of the Bournemouth Constitutional Association, and served his town first as councillor, then as alderman, and finally as mayor. The honour of knighthood was conferred on him in June, 1928. He was an active member of the British Medical Association, being member of the Dorset and West Hants Branch Council in 1904, and president of the Dorset and West Hants Branch in 1909. A man of many and varied interests, he held high and honoured positions in Freemasonry, and the directorship of various electric supply companies; he was also a trustee of the Kennel Club. He is survived by his widow.

Dr. ALBERT TRONSON OZZARD, late of the British Guiana Medical Service, who died on February 1st, obtained the diploma M.R.C.S. in 1886, and the L.S.A. in the following year. He had been a member of the British Medical Association for many years, and was president of the British Guiana Branch from 1922 to 1924. We are indebted to Dr. J. H. Conyers, late Surgeon General to British Guiana, for the following appreciation. Dr. A. T. Ozzard had served the colony for the long period of forty years (1887–1927), and had filled with distinction the various posts of district medical officer and resident surgeon to the Suddie and Georgetown Public Hospitals; he had also acted as surgeon general. To us, his colleagues, Ozzard was known as a keen scientific worker, and however great the routine demands of his work he always found time to call in the powerful aid of his microscope in the diagnosis of obscure

cases. He was one of the colony's earliest workers on the subject of ankylostomiasis, and the good work of Ozzard, Ferguson, and others of the British Guiana Medical Service on this subject led the Rockefeller Commission to start in British Guiana its earliest antihookworm campaign. Ozzard's studies in blood pathology led to the discovery of the *Filaria ozzardi*, so named by Sir Patrick Manson. Such is the brief record of a strenuous life in a tropical climate, broken by attacks of grave illness. His last work was the investigation of a severe epidemic of malaria in the upper reaches of the Demerara River at the end of 1926. Unfortunately he contracted the infection, and this was the immediate cause of the final breakdown in health, which lasted until his death. Our sympathies are with his widow, daughter, and two sons.

JOSEPH BROWNLIE WALLACE, who died at Clapham Common on February 22nd, graduated M.B. and C.M. at the University of Glasgow in 1888. After holding a house appointment in the Glasgow Eye Infirmary and acting for two years as an assistant he commenced practice in 1891, and continued in active work until the day of his sudden death, except for a serious breakdown of his health in 1923. There can be little doubt that this failure was due to overstrain during the war. He then undertook, in addition to his own large practice, the work of some of his colleagues absent on active service, and he acted on the emergency staff in the air raids. Wallace was a man in whom independence of character and steady judgement were combined with much kindness of heart and gentleness of manner. Absorbed in his professional work and a happy family life, he had little time for outside interests, but he enjoyed to the full extent the affection and confidence of a wide circle of patients and the respect of his colleagues. He held the rank of honorary captain in the R.A.M.C.(T.), and was Admiralty surgeon and agent in one of the London districts.—C. O. H.

We regret to announce the death, at the age of 39, of Dr. SAROZ KUMA SANYAL, which took place in Palestine on January 29th. Dr. Sanyal obtained his medical education at the London Hospital, and in 1915, after qualifying M.R.C.S., L.R.C.P., joined the army, serving with His Majesty's Forces in France till 1918, and in Mesopotamia till 1921. On demobilization he proceeded to Ammam, Transjordania, Palestine, where he built a hospital, and, with the help of an Arab staff which he trained himself, carried on medical work among the Bedouins. He was held in great esteem by the people among whom he worked. He is survived by a widow and one son.

The Services.

MEDICAL APPOINTMENTS TO THE KING.

Colonel T. G. F. Paterson, D.S.O., I.M.S., has been appointed Honorary Physician, and Colonel E. F. Mackie, O.B.E., V.H.S., Honorary Surgeon to His Majesty the King, with effect from September 24th, 1928, and September 28th, 1928, respectively.

TERRITORIAL DECORATIONS.

The Territorial Decoration has been conferred on Lieut.-Colonel John K. Lund and Major Henry J. D. Smythe, M.C., of the R.A.M.C.(T.).

DEATHS IN THE SERVICES.

Deputy Inspector-General Isaac Henry Anderson, R.N.(ret.), died at Twyford, Winchester, on February 2nd, aged 80. He was educated at Queen's College, Belfast, and graduated as M.D. in the late Queen's, afterwards the Royal, University of Ireland in 1869, also taking the L.R.C.S.Ed. in 1871. He entered the navy in September, 1871, became staff surgeon in 1883, and attained the rank of fleet surgeon on May 19th, 1892, retiring with an honorary step of rank as D.I.G. on May 23rd, 1902. He served on H.M.S. *Salamis* in the Egyptian war of 1882, receiving the medal and the Khedive's bronze star; and subsequently at Suakin, in the Eastern Sudan campaign of 1884, gaining a clasp to the Egyptian medal. In 1894 he was in charge of the naval hospital at Simonstown, and received the thanks of the Admiralty for services rendered at the Cape of Good Hope Hospital during the epidemic of fever which occurred after the Benin expedition. He received a Greenwich Hospital pension for good service on April 10th, 1917.

Medical News.

THE next evening reception at the Royal Society of Medicine will take place on Wednesday, March 13th. Fellows and their friends will be received in the library at 8.30 p.m. by the President and Lady Dawson of Penn. At 9.15 p.m. Dr. Leonard Williams will give an illustrated address on Napoleon II. Various objects of interest will be exhibited in the library.

AT the meeting of the Pharmaceutical Society of Great Britain to be held in the lecture theatre at 17, Bloomsbury Square, W.C., on Tuesday next, March 12th, at 8 p.m., a lecture will be given by Sir Herbert Jackson, F.R.S., Director of Research, British Scientific Instruments Research Association, on the nature of the changes which take place in various forms of glass. Medical friends of members will be welcomed.

THE Fellowship of Medicine announces that on March 11th Dr. F. W. Price will lecture on pitfalls in cardiology at the Medical Society of London, 11, Cavendish Square, W.1, at 5 p.m. On March 13th, at 4 p.m., Dr. W. J. O'Donovan will give a demonstration at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C.1, on the treatment of skin diseases by light therapy: indications and limitations. On March 14th, at 11 a.m., Mr. S. L. Higgs will give a clinical demonstration at the Royal National Orthopaedic Hospital, and on the same date at the Infants Hospital, at 4 p.m., Dr. Eric Pritchard will give a clinical demonstration of cases illustrative of the difficulties arising in connexion with digestive disturbances in infants. There is no fee for attendance at any of these lectures and demonstrations. From March 11th to 22nd there will be a course in orthopaedics at the Royal National Orthopaedic Hospital; instruction will continue throughout the day, Monday to Saturday inclusive. During this period also there will be a course at the Royal Eye Hospital, instruction being given daily from Monday to Friday inclusive at 3 p.m. The following courses will be held in April: a practitioners' course at the London Temperance Hospital; tropical medicine at the London School of Hygiene and Tropical Medicine; electro-therapy at the Royal Free Hospital; medicine, surgery, and gynaecology at the Royal Waterloo Hospital; and neurology at the West End Hospital for Nervous Diseases. Copies of all syllabuses, and details of the general course of work in the affiliated London Hospitals, are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A THREE months' course of lectures and demonstrations in clinical practice and in hospital administration for the diploma in public health will be given by the medical superintendent, Dr. F. H. Thomson, at the North-Eastern Hospital of the Metropolitan Asylums Board, St. Ann's Road, Tottenham, N.15, on Mondays and Wednesdays at 4.45 p.m., and alternate Saturdays at 11 a.m., beginning on Monday, April 8th. The fee for the course complying with the revised regulations of the General Medical Council is £4 4s., but a course under the old regulations can be taken for £3 3s.

IN connexion with the annual congress of the Royal Sanitary Institute to be held in Sheffield from Monday, July 15th, to Saturday, July 20th, 1929, a health exhibition will be held in the Cutlers' Hall in that city. The exhibits will include appliances and materials used in the various branches of hygiene (personal and collective) and sanitation, and in housing. Sections will be devoted to hospital design and construction, to public health equipment and to such matters as rat extermination, tropical hygiene, bacteriology, and health propaganda. Information regarding the exhibition may be obtained from the Secretary of the Institute, 90, Buckingham Palace Road, S.W.1.

WE are asked to state that hospitals situated within eleven miles of St. Paul's desiring to participate in the grants made by King Edward's Hospital Fund for London for the year 1929 must make application before March 31st to the honorary secretaries of the fund at 7, Walbrook, E.C.4 (G.P.O. Box 465A). Applications will also be considered from convalescent homes which are situated within the above area, or which, being situated outside, take a large proportion of patients from London.

THE People's League of Health has issued in pamphlet form a verbatim report of the speeches made by its deputation to the Minister of Health on December 4th, 1928, on the effect of noise on the health of the community. The proceedings of this deputation were reported in our columns on December 8th, 1928 (p. 1053).

THE Chadwick Trustees invite applications for two travelling scholarships of £400 a year each, to be awarded next July, one in sanitary science and the other in municipal

engineering; they are intended to enable their holders to study the methods in use in foreign countries for the prevention of disease and the improvement of public health, or the details of sanitary administration and engineering in urban or rural areas. Candidates must be British subjects between the ages of 25 and 30, who have graduated in a British University, or can produce evidence of ability to prosecute methodical study and research. Applications should be made by letter, before March 25th, to the Clerk of the Chadwick Trustees, at 204, Abbey House, Westminster, S.W.1, from whom more detailed information may be obtained.

THE Sections of Urology, Pathology, and Therapeutics of the Royal Society of Medicine will hold a joint discussion on urinary antiseptics, at 1, Wimpole Street, W., on Thursday, March 21st, at 8.30 p.m.

THE first international congress relating to medical services in connexion with aviation will be held in Paris from May 15th to the 20th. The subjects to be discussed include: the transport of wounded in war, the medical uses of aviation in peace, and the physiology of aviators. Further information may be obtained from the general secretary, 35, Rue François-Ier, Paris VIIIe.

THE thirty-eighth congress of the French Association of Surgery will be held in Paris on October 7th under the presidency of Dr. Tixier of Lyons, when the following subjects will be discussed: Indications for, and results of, osteosynthesis in the treatment of: Pott's disease, introduced by MM. Rocher of Bordeaux and Sorrel of Paris; evolution and treatment of wounds of the tendons of the hand, introduced by MM. J. C. Bloch of Paris and P. Bonnet of Lyons; and surgical treatment of pulmonary tuberculosis, introduced by MM. Lardennois of Paris and Bérard of Lyons.

THE eighth congress of the International Society of Surgery will be held at Warsaw from July 22nd to 25th, under the presidency of Professor Hartmann of Paris. Special railway concessions are available, and arrangements are being made for a party to travel to Warsaw by ship from Zeebrugge, calling at Copenhagen, Riga, Helsingfors, and Stockholm. Further information may be had from the general secretary, Dr. L. Mayer, 72, Rue de la Loi, Brussels.

THE fifth English-speaking Conference on Maternity and Child Welfare will be held at the Friends House, Euston Road, N.W., from July 3rd to the 5th, when the subjects for discussion will be: the care of the child between the ages of 1 and 5; maternal mortality and morbidity; the establishment of special venereal disease clinics for women and children in connexion with maternity and child welfare departments; and the suffering entailed on mothers and young children by prolonged waiting in out-patient departments. Lectures and film displays on child welfare will be given and visits will be paid to child welfare institutions. Further information may be obtained from Miss J. Harford, National Association for the Prevention of Infant Mortality, Carnegie House, 117, Piccadilly, W.1.

THE thirteenth international congress of ophthalmology will be held at Amsterdam from September 5th to 13th under the presidency of Professor van der Hoeve of Leyden, when the following papers will be read: geographical distribution and control of trachoma, etiology and non-operative treatment of glaucoma, and diagnosis of suprasellar tumours.

THE third congress of the French Societies of Oto-neuro-ophthalmology will be held at Bordeaux under the presidency of Professor Portmann from May 17th to 20th, when a discussion will be opened by Drs. Halphen, Moubrun, and Tournay of Paris, on headaches in oto-neuro-ophthalmology.

THE March issue of *The Prescriber* is devoted to spa treatment. Its contents include articles on the scientific application of mineral waters, baths, and douches; accessory spa treatments; and environment as an aid in this connexion. Dr. Fortescue Fox contributes a note on the scope of waters internally and externally, and there is a descriptive list of spas in Great Britain, Ireland, and New Zealand, with numerous illustrations.

DR. HAVEN EMERSON, professor of hygiene at Columbia University, New York, has been invited by the Greek Government to investigate sanitary conditions in Greece.

THE Umberto Primo prize of 3,500 liras, offered by the Rizzoli Institute of Bologna for the best work or invention relating to orthopaedics, is now open to medical practitioners of all countries. Further information can be obtained from the president of the institute.

PROFESSOR HAYASHI, dean of the Faculty of Medicine at Tokyo, has been nominated an officer of the Legion of Honour.

DR. TYTGAT of Ghent has been elected president of the Belgian Société de Chirurgie.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563, and 9564* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

PAINFUL SCAR.

"X. Y. Z." asks for suggestions for the treatment of a painful scar on the inner side of the foot, the result of an operation some years ago. The scar is about 4 in. long, and is still red.

ENURESIS.

"K." asks for any suggestions in the treatment of enuresis in a boy aged 15. Bed-wetting occurs practically every night, and has gone on since infancy. The patient is well developed and normal in other respects. The usual treatments have been tried, and drugs, such as belladonna, citrates, thyroid, etc., employed. The tonsils and adenoids were removed years ago.

GROWTH ON SPONGES.

MR. P. MAYNARD HEATH (London, W.1) asks for information about a disease of the domestic sponge characterized by the formation of a black growth filling the pores. The condition is unaffected by domestic cleansing.

ADMINISTRATION OF ULTRA-VIOLET RAYS.

"A. M." asks: (1) What is the most suitable form of heating for a small room in which an ultra-violet ray lamp of the combined mercury vapour and carbon-tungsten type is installed from the point of view of the preservation of the lamp itself, and also from that of the effectiveness of the rays in treatment? (2) At what temperature should the room be kept for the safety of the lamp? (3) Is it not the case that an atmosphere heated by a steam radiator will reduce appreciably the effectiveness of the rays on account of moisture and dampness which must necessarily result from this form of heating? (4) What is the simplest method of testing the efficiency of the lamp after twelve months' use?

TREATMENT OF CHRONIC CONSTIPATION.

DR. T. W. ROTHWELL (Sedbergh) writes: I was called to see a workhouse patient suffering from chronic non-obstructive constipation. I first ordered him one ounce of castor oil with no result. I then gave him a tablet composed of aloin 1/4 grain, phenolphthalein 1/2 grain, ipecacuanha 1/15 grain, strychnine 1/100 grain. Of these he had three, three times a day for two days with no benefit. I then ordered an enema, with medium result, but he was still absolutely constipated, with no signs of an obstruction. I then gave him the following pill:

℞ Pulv. aloes	16 parts
Pulv. colocynth.	8 ,,
Pulv. jalap verum	8 ,,
Pulv. saponis cast.	8 ,,
Ol. caryophylli	1 part

Weight of pill 5 grains.

Of these he had three pills thrice daily for three days, with no result. I then put him on calomel 6 grains every four hours. After taking 36 grains he had had no result. Intending to give him 1 minim of croton oil the next morning, I learnt that he had had a copious motion after the administration of 42 grains of calomel. Does this constitute a record for calomel dosage? Also what is the poisonous dose of calomel, if any? Can any of your readers inform me what would be a safe and efficient treatment of this kind of constipation? The man is 45 years old and is inclined to be melancholic; he is quite satisfied with an enema as a means of securing a bowel movement.

SOUND-PROOF DOORS.

DR. H. M. SPEIRS (Diss, Norfolk) writes: An easy and practical method of overcoming this difficulty is to nail a sheet of "celotex" (which is a wood pulp sheeting, made from sugar-cane) over the door. I have done this with success.

TREATMENT OF UNCONTROLLABLE COUGH.

DR. A. J. COLBY TINGEY (Hastings) writes in reply to "D. H. A.": I have found chloretone inhalant (Parke, Davis) effective in cases of incessant cough due to irritable conditions of the nose and throat. It should be used as a spray with a nebulizer.

INCOME TAX.

Allowances.

"D. P. H." has been assessed to pay £8 12s. in respect of £103 10s. received for temporary service as assistant medical officer of health; the amount appears to be excessive.

*** Evidently, although the earned income relief has been given, nothing has been deducted in respect of the personal allowance of £135 per annum. Unless that allowance has been received as a set-off against other income for the same year, it should be claimed promptly. The travelling expenses of 7s. 6d. per week were apparently incurred between the residence (temporary or permanent) and the place of employment; if so, they are not allowable, but if they were incurred in going about to do the work for which the remuneration was received the total amount is allowable.

Subletting Part of Premises.

"TAXPAYER" owns the premises containing his surgery and has let the upper part as an unfurnished flat. Must the rent received be returned for assessment to tax?

*** The point does not seem to be covered by direct judicial authority, but there appears to be no ground on which the authorities can claim that such a rent should be returned for assessment. We assume that "Taxpayer" pays the rates, but does not supply services such as lighting, cleaning, etc. On the other hand, the rent received is a material factor in deciding what proportion of the Schedule A assessment on the premises can be deducted in arriving at the profits of the practice. We do not mean that the appropriate deduction is necessarily the excess of that assessment over the net rent received, but the greater that amount the stronger is the authorities' argument for some restriction of the amount to be allocated to the "surgery."

Car Transaction.

"W. M. W." bought a new car in 1926 for £360. He has now sold it for £100, and bought a second-hand car for £250. What can he claim?

*** He cannot claim more than the out-of-pocket expenditure—that is, £250−£100=£150. He should, however, retain a note of the facts, because if the next car he buys should be a new car costing more than £250, these facts should assist him in resisting any suggestion that the second replacement involved an improvement of his car equipment.

Cash Receipts or Bookings.

"A. G. M." has been informed by his local inspector of taxes that "income tax is assessed now on the 'work done' basis and not on the actual payments received." Is this correct?

*** We are not aware of any general change in the attitude of the Inland Revenue Department on this matter. That attitude we have understood to be that, although the value of the year's bookings is strictly correct, the amount of the cash receipts is accepted as being reasonably equivalent taking one year with another, provided that there are no special circumstances which suggest that the amount of fees being booked is increasing—in that case the cash receipts tend to lag behind the value of the bookings, and do not afford a fair index to that value.

LETTERS, NOTES, ETC.

TREATMENT OF INFLUENZA.

DR. W. BASTIAN (Coventry) writes: I have read with interest the note by Dr. Garry Simpson on March 2nd (p. 430) concerning the treatment of influenza with the combination of drugs as first suggested by Sir Archdall Reid of Southsea some years ago. During the recent severe epidemic of influenza, and previously, I have had the same experience as Dr. Garry Simpson, and know of no better treatment, even in the case of quite young children. The sweating is so profuse that one can only suppose that therein lies the merit of the treatment, in that the toxins are excreted in the sweat. I am aware that this idea has been laughed at by some pathologists, but what alternative explanation is there? I have also found this compound powder (aspirin, phenacetin, and pulv. ipecac. co.) the most useful in the early stage of all acute specific diseases, and for measles it is the ideal treatment in suitable doses.

EPIGASTRIC PAIN IN INFLUENZA.

DR. C. MACKAY SEWARD (West Lothian) writes: During the last two epidemics of influenza I have noticed the fairly frequent incidence of the symptom of epigastric pain. This appears to arise from any of three causes: (1) Neuralgia of the nerves supplying the epigastrium may be present when there is hyperalgesia, unaccompanied by muscular tenderness or gastric symptoms. (2) The pain may be muscular, when the condition may be either an acute fibrositis, unaccompanied by hyperalgesia and preceding the onset of coughing or vomiting, or it may take the form of a muscular strain, as a result of frequent coughing or vomiting. My criteria for a muscular origin of the pain were: (*a*) pain and tenderness brought on or increased by use of the rectus, the upper segments of which seem most commonly to be involved, as in lifting the head from the pillow; and (*b*) tenderness elicited by grasping the muscles laterally, without backward pressure, as suggested by Hutchison. The third cause is acute gastritis, when vomiting is an early symptom, with deep epigastric tenderness and, sometimes, diarrhœa.

CALCIUM LACTATE AS A MUSCULAR TONIC.

DR. G. P. BARFF (Ash Vale) writes: Five years ago I noted for the first time some surprising results in the metabolism of the voluntary muscles during the administration of calcium lactate to middle-aged and elderly patients. In the case of one, aged 73, who had been an athlete and rowing man in his youth, the arm muscles before treatment were very flabby from old age and want of use, while the pectoral and back muscles could not be made out. No exercises were given for the muscles; he walked, as usual, about a mile a day. After taking the calcium lactate mixture for a week, after tea, the arm muscles became very much more prominent, the biceps bunched up well on contraction and hardened, and, moreover, old rowing muscles not seen by him for many years reappeared in the forearms, while the pectoralis major muscles filled out obviously, and later the back muscles reappeared. He was under treatment for about three weeks, and wrote twelve months later to say his arm muscles were still in evidence. He also experienced a feeling of fitness. Further investigations led me to the belief that a simple saline remedy of this kind will increase the tone of the muscles in conjunction with dieting.

ULTRA-VIOLET LIGHT TREATMENT OF BED-SORES.

DR. ELIZABETH C. MUDIE (Glasgow) writes: A patient suffering from paralysis of the right side was irradiated by me with the quartz mercury vapour lamp in order to control a very large bed-sore which covered the right ischial tuberosity. To my great surprise not only has the local condition cleared up, but the whole situation has vastly improved. The patient can now control the bladder, has a very large degree of movement in the arm and leg, can turn almost without assistance, and has markedly improved in mental acuity. She is 70 years old and weighs 16 st. I should be interested to hear if others have tried actino-therapy in these so-called hopeless cases.

THE NATURE OF DISEASE.

DR. GORDON WILSON (Thurlstone, near Sheffield) writes: May I add another to the definition of disease cited by Sir Humphry Rolleston in your issue of February 16th (p. 281)? So far as I am aware it is original, but I may be wrong. "Disease is an unsatisfactory reaction of a particular individual to his environment, and death is the absence of all reaction to his environment." The "unsatisfactoriness" of the reaction may be evident to the individual himself or to society only. It would take too long to write out the full implications of this definition, but personally I find it so useful that, like the pragmatist, I regard it as true.

ULCERATIVE ENDOCARDITIS.

DR. G. ARBOUR STEPHENS (Swansea) writes: Will you allow me to point out in connexion with the interesting case of ulcerative endocarditis reported by Drs. Macdonald and MacNab on February 23rd (p. 348), that, although three of the valves showed signs of inflammation, there were no murmurs heard. Further, the opening of the tricuspid valve was interfered with by a clot, and, according to all theories regarding the cause of the heart sounds, a very marked murmur ought to have been heard. The "gallop rhythm," as well as the "reduplication of the sound," can be accounted for by the modification of the pericardial fluid, which was increased in quantity, as well as altered in quality, and I venture to claim this case as one which supports my theory of the heart sounds.

THE INVENTOR OF ESPERANTO.

A CORRESPONDENT has drawn our attention to the fact that Dr. Zamenhof, the inventor of Esperanto, who was born in 1859, died in 1917, and therefore did not live to celebrate his seventieth birthday, as implied in our last issue.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50, 51, 52, 53, 56, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 59.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

227. Agranulocytic Pharyngitis following Antisyphilitic Treatment.

A. BOCAGE and L. FILLIOL (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, January 3rd, 1929, p. 1807) report a fatal instance of agranulocytosis in a case of syphilis. The patient, an anaemic man aged 30, developed necrotic pharyngitis three weeks after the termination of the first course (ten weeks' duration) of novarsenobenzol-bismuth injections; during this course he had had one slight febrile attack. The necrotic pharyngitis was severe, and was accompanied by rigors, headache, and dysphagia, but the patient did not mention it when he came for the second course of injections after an interval of four weeks. During the night following the injection of the second dose of this course the patient had rheumatic pains in the legs, with fever; the next day the gums were bleeding and purpuric patches appeared on the legs. Two days later he was admitted to hospital in a state of severe toxaemia; he was sallow, his features were drawn, there was severe dysphagia, and speech was very painful. The patient had a constant flow of blood-stained saliva, and expectorated thick mucus. The teeth were covered with blood clot; necrotic patches were seen on both tonsils. The temperature rose to 104.4° F. and intestinal haemorrhages recurred. Transfusion and the administration of haemostatics failed to avert death. The necropsy showed the characteristic changes in the bone-marrow cells described by Schultz, accompanied by large numbers of a Gram-positive micro-organism resembling *B. perfringens*. The authors believe that an acute bacterial infection occurred during the first course of injections. The patient was recovering spontaneously from this infection when the resumption of the antisyphilitic treatment caused an aggravation of the bacterial infection. Novarsenobenzol was probably responsible for the haemorrhages, but, although the haemolytic action of *B. perfringens* is well known, the authors, in the absence of blood examinations before and after the initial pharyngitis, cannot be sure that this organism was the original cause.

228. Migraine.

C. W. MCCLURE and MILDRED E. HUNTSINGER (*New England Journ. Med.*, December 27th, 1928, p. 1312), following the study of a series of 78 patients, discuss the etiology, symptomatology, and treatment of migraine. Its onset at periods other than adolescence is said to be more common than is generally recognized, and paroxysmal headache is frequently the only symptom. The occurrence of positive cutaneous food protein reactions points to the advisability of withholding reacting proteins from the dietary. Disturbances in lipoid metabolism, abnormal liver function, and positive protein sensitization reactions were definite pathological findings, suggesting that hepatic dysfunction plays an important part in the production of symptoms, and that the condition bears some relation to the etiology of chronic cholecystitis and peptic ulcer. The authors point out the value of intraduodenal therapy—namely, the introduction into the duodenum through a tube of 30 c.cm. of 33 per cent. magnesium sulphate solution at weekly intervals, and the importance of keeping the patient well nourished, the degree of relief being often in direct proportion to the gain in weight and strength. The correction of eye strain, working conditions, and other underlying causative factors must receive attention, but the adoption of surgical measures to relieve symptoms without careful forethought is deprecated.

229. Demineralization of Bones in Pulmonary Tuberculosis.

ARGUING from the fact that in bone tuberculosis a specific inflammation results in decalcification, A. VALLEBONA (*Rif. Med.*, December 17th, 1928, p. 1656) has endeavoured to determine whether there is any loss of mineral salts in the long bones of sixteen patients suffering from pulmonary tuberculosis who were examined radiologically. In each case Koch's bacillus was present in the sputum, and the patients reacted positively to all the biological tests. Each tuberculous patient was compared with a healthy individual of the same sex, and about the same age and weight, the skeletal and muscular systems being approximately comparable; in the control cases no indications of tuberculosis were found in the history, physical examination, and radiography. X-ray photographs of the forearms of the patient and the control were taken on the same plate. The author concludes that although demineralization was apparent in certain cases of pulmonary tuberculosis, it was not at all constant. In the cases in which the tuberculosis was slight and localized there was no bony change; when the local lesion was severe, but without general distribution, no demineralization was seen. Where a grave local lesion was present together with general distribution, and particularly in cases of long-standing disease, a definite bony change was obvious. This was seen most clearly in adolescents.

230. Early Diagnosis of Scarlatinal Nephritis.

E. BRASIELLO (*Il Policlinico*, Sez. Prat., January 14th, 1929, p. 41) records his observations on 123 cases of scarlet fever, 46 of which had renal complications. In 43 of these it was possible to determine the onset of the renal lesion by haematological examination before any indication of it could be found in the urine or in the patient's general condition. In the great majority of cases (about 90 per cent.) the renal change could be discovered ten to twelve days before it was manifested by the examination of the urine or the general condition, while in the remainder the only indication of a renal lesion was a more or less marked retention of urea and sodium chloride without anything abnormal being found in the urine. In such cases, to which the term analbuminuric uraemia or analbuminuric oedema has been applied, a careful watch should be kept for possible damage to the kidney. The first sign of impaired renal function is given by a simultaneous rise in the urea and sodium chloride in the blood as well as of the systolic blood pressure, and it is only when the renal lesion has become more or less pronounced that it is detected by examination of the urine and general condition.

231. Infectious Mononucleosis (Glandular Fever).

E. SCHWARZ (*Wien. klin. Woch.*, January 24th, 1929, p. 98) suggests that glandular fever, or infectious mononucleosis, is a definite clinical, epidemiological, and pathological entity produced by a lymphotropic virus which evokes the following symptoms: fever, swelling of lymph nodes and spleen, and a lymphoblastic plasma-cellular blood picture. Some have suggested that it is merely a sequel of whooping-cough and of rubella; one writer has seen, in Brazil, cases of fever following tick-bites in which there developed a diffuse itching erythema, generalized swelling of lymph nodes, accompanied by lymphocytosis, with excess of plasma cells in the blood picture. Further, many patients with glandular fever exhibit a characteristic sore throat. Etiologically and [illegible] disease closely resembles an acute [illegible] recent observations compel the [illegible] er relationship or etiological identity.

232. Optic Neuritis in Herpes Zoster.

J. DUPORT (*Thèses de Lyon*, 1927–28, No. 37) records a personal case, in a woman aged 70, and has collected eight similar cases from the literature, of ophthalmic zoster followed by optic atrophy and complete blindness. Several explanations have been advanced of this occurrence—namely, that it is a mere coincidence, a reflex disturbance, an irritation of the branch connecting the ophthalmic with the optic nerve, and herpetic meningitis. Duport is in favour of the theory of there being an intracranial meningitis with a secondary optic meningitis and neuritis. The diagnosis is made by the presence of the vesicular eruption or the scars of herpes and ophthalmoscopic examination, which usually shows a unilateral lesion. Of Duport's nine cases, seven were unilateral and only two bilateral. The prognosis should always be guarded, vision being either entirely lost or considerably diminished. Treatment consists in the administration of arsenic and strychnine, associated with radiotherapy in cases of persistent pain.

233. Causes of Sudden Death.

R. JAFFÉ (*Deut. med. Woch.*, November 30th, 1928, p. 2010) deprecates the too free use of the diagnosis "heart failure" in cases of sudden death, on the grounds that important information is often unobtainable unless a careful necropsy is performed. He gives details of seventy-three inquests in cases of sudden death in which the causation was obscure, and advocates more detailed investigation when "status lymphaticus" is apparent in otherwise healthy children. He discusses the probable way in which death occurs in cases of high arterial pressure, coronary sclerosis, and other such conditions, emphasizing the point that what is frequently obscure is why a heart, which has continued to

function in spite of anatomical change, has for some hidden reason been brought to a standstill. He draws attention to the greater variety of pathological and functional conditions which may be concerned, and adds that these problems have considerable importance from the point of view of insurance, as well as from that of medical pathology.

234. Post-encephalitic Adiposis Genitalis.

O. COZZOLINO (*La Pediatria*, January 1st, 1929, p. 19) reports a case of limited adiposis following an attack of encephalitis a year previously. A boy, aged 8, suffered from diplopia, sleepiness, choreic manifestations, diarrhoea, progressive mental weakness, and polyuria, followed some months later by progressive adiposis especially affecting the nates and genital area. The genital organs were small, but the testes were in the scrotum. While in hospital he put on nearly 3 lb. in sixteen days. There was no evidence of pituitary tumour, but a radiogram showed some narrowing of the sella turcica. There was no reaction after pilocarpine and no signs of suprarenal or alimentary glycosuria; some increase of pressure followed the administration of adrenaline. The author discusses the nature of the lesion and refers to other cases of this post-encephalitic sequel.

235. Syphilitic Phlebitis.

S. GREZZI (*Rev. méd. Latin-Amér.*, December, 1928, p. 241), who records a typical case of bilateral phlebitis in the secondary stage in a man aged 22, and has collected forty-eight cases from the literature, states that syphilitic phlebitis may occur in both hereditary and acquired syphilis. Its rarity is in striking contrast with the frequency of syphilitic arteritis. The affection is commonest in the male sex and in the superficial veins of the lower limbs. The symptoms are scanty, the most prominent being the aggravation of the pain and loss of frictional capacity in the limb at night. The other diagnostic features are the lack of local signs, the large number of veins attacked, the absence of embolism, the previous history of syphilitic infection or a positive Wassermann reaction, and the action of specific treatment. *Treponema pallidum* has been found in the affected veins. The condition must be distinguished from lymphangitis and erythema nodosum. Combined specific treatment with arsenical or bismuth preparations has an immediate effect, and must be associated with rest in bed with the limb in a splint.

Surgery.

236. Surgical Treatment of Pulmonary Abscess.

R. FONTAINE (*Arch. Méd.-Chir. de l'Appareil Respirat.*, October, 1928, p. 400) classifies pulmonary abscess according as it is due to (1) acute inflammation (pneumonia or broncho-pneumonia); (2) chronic bronchitis or bronchiectasis; (3) suppurative embolism; (4) foreign body in the bronchi; (5) penetrating wound of the lung; and (6) hepatic abscess. An abscess may also develop around a subjacent malignant tumour, or may follow surgical interventions such as tonsillectomy, gastric operations, or even appendicectomy. Diagnosis is often difficult, but stereoscopic skiagraphy after the intratracheal injection of lipiodol and bronchoscopy are valuable diagnostic aids. Surgical methods of treatment of acute pulmonary abscess are: bronchoscopy with aspiration of abscess, which has usually to be repeated frequently; artificial pneumothorax; phrenicectomy; and pneumotomy, which has given the best results in carefully selected cases. The treatment of chronic abscess is entirely surgical; of indirect methods, bronchoscopy, artificial pneumothorax, and phrenicectomy are seldom successful. Stripping the parietal pleura and thoracoplasty have been effective in many cases, but simple drainage is useless. Of the two direct methods, lobectomy in one stage is very dangerous; performed in two stages it is less risky, but very difficult, and the mortality is high. Pneumectomy by means of the thermo-cautery, in a series of 45 patients, resulted in 69 per cent. of "cures"; 11 patients died and 10 of the "cured" patients were left with bronchial fistulae. Fontaine concludes that, in chronic pulmonary abscess, bronchoscopy and artificial pneumothorax are useless unless combined with other measures. Treatment by collapse should always be performed as a preliminary, and only two subsequent operations should be considered: (1) stripping the parietal pleura, and (2) thoracoplasty preceded by phrenicectomy. Removal of the parietal pleura is suitable only in recent cases, in which the abscess is apical; other cases require thoracoplasty, which is not more dangerous than stripping the pleura. Collapse procedures are contraindicated when serious pleural complications are present; when it fails, pneumectomy should be performed, or a two-stage lobectomy, if possible. The mortality from pulmonary abscess is so high that Fontaine considers that surgeons are justified in taking great risks.

237. Deformity in Infantile Paralysis.

W. R. MACAUSLAND (*New England Journ. Med.*, January 3rd, 1929, p. 18) emphasizes the importance of prevention rather than correction of defo[illegible] infantile paralysis. The development of [illegible] upon a number of factors, such as muscle imbalance due to paralysis of certain groups of muscles, ligamentous and tissue contraction, habit posture in the effort to alleviate pain, and gravity. Effort at prevention should thus be directed to keeping the limbs in correct positions: the foot at right angles to the leg, the hip and shoulder in abduction, the knee in extension, the elbow in right-angled flexion, and the wrist in hyperextension. A fracture board under the mattress, and supports beneath the angles of the scapulae, are recommended to keep the spine in extension. When, later in the course of the disease, it is known which groups of muscles are mainly affected, plaster bandages or light mechanical appliances are used to keep the limb in an attitude of over-correction. If the paralysed muscles are kept relaxed the greatest possible return of power is ensured. Still later, in convalescence, the prevention of spinal curvature is very important, since it may arise insidiously and become a definite deformity before the trouble is evident. Correction becomes necessary immediately a malposition is recognized; neglect leads not only to increase of the actual defect, but to deformities in related parts of the body. Manipulations, fasciotomy, tenotomy, and osteotomy are among the simpler surgical procedures indicated, but for the restoration of muscle balance tendon transplantations are of value in selected cases. Transplantation of the tibialis anticus into the cuboid for varus deformity, of the peroneal for valgus deformity, accompanied by astragalectomy, and of the sartorius for quadriceps paralysis, are among the most successful operations. [illegible] as an excellent stabilizi[illegible] perform astragalectomy.

238. Cysts of the Psoas Bursa.

ACCORDING to C. DE GÉRY (*Bull. et Mem. Soc. Nat. de Chir.*, December, 1928, p. 1466) cysts of the psoas bursa are of rare occurrence and may be classified in four groups: the purulent; the tuberculous; the syphilitic; and simple cysts. The last of these are most frequent, providing twenty-four cases out of thirty-three in the author's experience. The size of the cyst ranges from that of a hen's egg to that of an infant's head; there are also considerable variations in shape. Frequently the cyst is as firm and unchanging in size as a solid tumour, the walls containing the cystic fluid being very thick. Communication of the hygroma and the hip-joint has been noticed in about 50 per cent. of cases; it is known that such a communication of the serous bursa of the psoas with the adjacent joint cavity is often found, most frequently in older patients. Apart from pain, more or less intense, and due to the compression or displacement of the crural nerve, there are no functional disturbances, the movements of the hip being unimpaired. The cyst usually contains a thick yellow fluid, and sometimes foreign cartilaginous bodies which, by their number and size, may give rise to complications. The causation of chronic hygromas of the psoas bursa is obscure; rheumatism, syphilis, tuberculosis, and muscular trauma have all been cited as possible factors. Treatment may consist in the puncture of the cyst, aspiration of the fluid, and the washing out of the cavity with an antiseptic fluid such as iodine. The complete removal of the cyst is preferable when possible.

239. Fatal Perforation in Paratyphoid B Fever.

A. POP (*Zentralbl. f. Chir.*, January 12th, 1929, p. 77) describes an ambulant case of paratyphoid B infection in which perforation occurred. A man, aged 51, was admitted to hospital with symptoms of peritonitis. He had not consulted a doctor, although he had suffered occasionally from abdominal pain since 1925. There was no history of haematemesis nor of melaena. Four weeks before admission his illness commenced with anorexia, severe epigastric hunger pains, evening rigors, and diarrhoea followed by constipation. He had not discontinued work. Three days before admission he had a sudden severe pain in the right iliac fossa, accompanied by vomiting and fever. He grew worse rapidly and was admitted with symptoms of acute obstruction; the pain was constant and there was distressing hiccup. The temperature was 102.1° and the pulse 96. The spleen was enlarged on percussion; the abdominal wall was rigid and there was dulness on percussion over the right lower quadrant, where there was tenderness on deep pressure. The recto-vesical pouch was obliterated and very tender. When the peritoneum was opened in the mid-line, faecal fluid

escaped; intestinal coils in the right iliac fossa were adherent and covered with purulent exudate. A perforation as large as a pea was found in the lower ileum; this was sutured and the peritoneum was drained. Serological tests showed a paratyphoid B infection. The patient died four days later. Pop refers to the rarity of perforation in paratyphoid B fever. He has found records of nine previous cases; five were due to paratyphoid A infection, the remainder to paratyphoid B. Two of the latter were ambulatory cases. Of nine cases of operation for perforated paratyphoid ulcer five patients recovered.

240. Bifid Renal Pelvis and Ureter.

REPORTING a case of this rare anomaly R. LE FUR (*Bull. et Mém. Soc. des Chir. de Paris*, January 18th, 1929, p. 72) distinguishes between (1) bifurcation of the ureter and renal pelvis, in which the ureter, single below, divides into two with two pelves, and (2) duplication of these organs, the two ureters opening separately into the bladder. There are varying degrees of this condition. In the first the ureter soon bifurcates into two large calyces, which reunite at the hilum. In others the bifurcation is more or less extensive, but there is still only a single vesical orifice for both ureters, which may reunite either near the bladder, at the middle of the ureter opposite the first sacral vertebra, or at the upper third of the ureter above the sacrum. In total duplication one of the ureters always enters the bladder at the normal point, while the other may open into the bladder, prostate, ejaculatory canal, or seminal vesicle. The two ureters are enclosed in the same sheath, and one is always above and never behind the other. Their calibre is ordinarily normal, and in cases of dilatation the lower ureter is usually the dilated one. Of the two pelves the upper is most frequently the smaller, and receives only the calyces of the upper fourth of the kidney. The two are usually separated by a marked prominence formed by a column of Bertin, and are always isolated from each other without any intercommunication. The kidney is elongated, and is sometimes divided into two parts by a depression. Changes in the blood vessels and hilum do not appear to be more frequent than in normal kidneys. Bilateral bifurcation of both ureters is much rarer than the unilateral type.

241. Erosion of Neck Vessels in Scarlet Fever.

J. D. ROLLESTON and W. G. SEARS (*Brit. Journ. Child. Dis.*, October–December, 1928, p. 281), who record two fatal cases which they had seen in the course of six months, state that erosion of the neck vessels giving rise to fatal haemorrhage is a very rare event and practically only occurs in scarlet fever and gangrenous angina. In scarlet fever the vessels liable to be involved are the external and internal carotid, superior thyroid, and lingual arteries, and the external or internal jugular veins. The haemorrhage from erosion of the vessel may be secondary to faucial ulceration or a cervical abscess, and may occur from the mouth, the ear, or the wound in the neck where the abscess was opened. Most of the recorded cases have been fatal, but recoveries have been reported after ligature of the common carotid or merely plugging the wound. The authors' first case was that of a male infant, aged 11 months, who in the course of a moderately severe attack of scarlet fever, complicated by suppurative cervical adenitis and otorrhœa, had profuse haemorrhage from the external auditory meatus and died in a few minutes. At the necropsy the bleeding vessel was not found, but the source of the haemorrhage was probably one of the veins in the neighbourhood of the cervical abscess. The second patient was a female child, aged 2 years, with a septic attack of scarlet fever, also complicated by suppurative cervical adenitis. In this case the haemorrhage took place from the wound where the cervical abscess had been opened, the internal jugular vein being the source of the haemorrhage.

242. Treatment of Hernia by Alcohol Injections.

F. WYSS (*Schweiz. med. Woch.*, January 26th, 1929, p. 85), who records the results of treatment of hernia with alcohol injections in 3,084 cases, states that this method was first introduced by Schwalbe in 1876, but received little attention owing to the excellent results of operative treatment. The procedure can be employed either in clinics or in out-patient practice; Wyss prefers the latter. A permanent cure is obtained in 91 per cent. of cases. The advantage of the method is that the patient is able to continue his work; he runs no risk, and in only 4 per cent. of the cases were there any complications, while such as occurred were not serious and cleared up entirely. The injections can be given irrespective of the patient's age and health, or of the duration and size of the hernia. Patients so treated can, in case of relapse, be operated on later with success.

Therapeutics.

243. Purine-base Diuretics in Angina Pectoris.

N. C. GILBERT and J. A. KERR (*Journ. Amer. Med. Assoc.*, January 19th, 1929, p. 201) believe that the purine-base diuretics are of very definite value in many cases of angina pectoris, and that their unpleasant effects may be eliminated in part by a careful study of the patient's individual reactions to the different preparations, to dosage, or to different methods of administration. A tabulated summary is given of the results produced by these drugs in a series of 86 ambulatory patients, none of whom were laboriously engaged, the effect on the pain being alone considered. Caffeine was not used in this series, the preparations employed, with their customary doses, being as follows: theobromine, 5 grains; theobromine sodium acetate, 10 grains; theobromine sodio-salicylate, 7½ or 10 grains; theophylline, 2 grains; theophylline sodio-acetate, 4 grains; and theophylline-ethylenediamine, 1½ to 3 grains. Four doses a day were usually given, but the number, as well as the dosage and time of administration, were changed, if necessary, in order to minimize ill effects. Other drugs were not used, with the exception of laxatives or purgatives when needed. The daily life of the patients was not altered, but owing to the frequency of attacks of angina a ter taking food they were cautioned to rest half an hour before and half to one hour after meals and to avoid gas-producing foods. The drug was given for three or four days and then discontinued for the same length of time; in most cases it was administered the first four days of each week and omitted the last three; this was done to avoid nausea or other unpleasant symptoms, and to prevent tolerance. The very definite risk of inducing tolerance was combated by alternating the preparations. Of the series only 14 patients received no relief from any of the drugs used; 7 of these were very neurotic, 3 had advanced coronary disease, and 1 had syphilitic aortitis. The authors agree with Heathcote that the order of intensity of vaso-dilator power is (1) theobromine, (2) theophylline, and (3) caffeine. They think that the clinical phenomena of angina pectoris can best be explained by the blood flow in the coronary vessels being inadequate to the needs of the heart muscle at the moment. They conclude that the purine-base diuretics are capable of producing an increased coronary flow, and that beneficial results can be expected from their administration, except when an increased coronary flow is precluded by advanced anatomical changes in the vessels.

244. Quinidine in Auricular Fibrillation.

AN attempt is made by J. PARKINSON and M. CAMPBELL (*Quart. Journ. Med.*, January, 1929, p. 281) to assess the value of quinidine from records of a study of twenty patients with paroxysmal and forty-four with established fibrillation, in which this drug seemed more useful than digitalis. They gave 5 grains of quinidine sulphate in tablet form by the mouth twice a day in paroxysmal cases; in established cases an initial trial dose was followed by increasing doses of 5 grains a day until 30 grains a day was being taken. Quinidine and digitalis were not given together, but in cases of congestive failure digitalis was given first, followed after an interval by quinidine. The authors found that the use of the drug is free from risk; they consider it the best method of treatment in paroxysmal fibrillation when the attacks are so long or frequent as to justify continuous medication, provided the patient is well in the intervals. In established fibrillation of recent onset they maintain that it is the treatment of choice, since in the absence of serious failure or much cardiac enlargement it often restores normal rhythm better than digitalis. They add, however, that treatment with digitalis is best in long-established fibrillation with a large heart, marked congestive failure, or active infection. In the absence of disease other than the arrhythmia, treatment with quinidine may be short, but it should be prolonged in cases with rheumatic or thyroid disease. It tends to postpone the tendency to cardiac failure or embolism, and if used at once on the onset of fibrillation in a patient in good health it is considered to be a safe and effective remedy.

245. Treatment of Syphilitic Aortitis.

R. HIFT (*Wien. klin. Woch.*, January 17th, 1929, p. 79) states that neosalvarsan, bismuth, and mercury succinimide have superseded the iodide treatment of syphilitic aortitis in preventing the occurrence of valvular damage and aneurysm; when combined these drugs yield the best results. Hift claims that 75 per cent. of his patients with mesaortitis have been rendered fit for work in this way, and are almost or entirely free from pain. He recommends that the Wassermann test be performed in every patient over the age of 30

who suffers from heart disease, though a negative result is not always conclusive. As regards treatment, the anatomical site of the syphilitic lesion is said to be less important than the subjective symptoms, the general health, and the state of the circulation. Death during treatment should not be attributed necessarily to specific medication; cases of sudden death have been observed in untreated mesaortitis. The only contraindications are grave ill health, "status angiosus," and evidence of circulatory failure. Mercury and bismuth are to be preferred in cases of moderate circulatory failure or more definite anginal conditions. For well-compensated cases, especially when the patient has had but little previous treatment, combined medication with salvarsan is recommended.

246. Dosage of Histamine.

L. M. GOMPERTZ and W. COHEN (*Amer. Journ. Med. Sci.*, January, 1929, p. 59) discuss the effect of smaller doses of histamine in stimulating gastric secretion. As the result of examining a series of patients, they conclude that histamine hydrochloride in doses of 0.25 mg. appears to be useful in all conditions where a safe and efficient gastric stimulant is indicated. This dose is said to be devoid of untoward effects, and therefore the previously recommended larger dosage of 0.5 mg. no longer seems necessary or desirable in diagnostic or therapeutic procedures. The authors think that their determination of the minimal effective dose paves the way for considering the possible use of the drug for therapeutic purposes in appropriate cases of impaired function of the gastric secretory glands. They add that the secretion and acidity resulting from injection of this small dose is considerably greater than that which follows the administration of a standard test meal.

247. Rectal Administration of Liver.

H. PULFER (*Deut. med. Woch.*, January 18th, 1929, p. 99) describes two cases of severe pernicious anaemia which were successfully treated with fresh liver administered per rectum. Both patients had an unconquerable dislike to liver, which caused nausea and vomiting if taken by the mouth except in amounts which were insufficient to effect any change in the blood. It was decided to employ clysters of 150 grams of fresh liver rubbed through a hair sieve and diluted with milk, 15 drops of tincture of opium being added; this enema was daily injected into the previously washed out rectum. The effect of this treatment was startling. In the first patient the haemoglobin rose in five days from 17 per cent. to 41 per cent., and the red cell count from 710,000 to 2,100,000; in a month the red cell count was 3½ millions and the haemoglobin percentage 86. In the second case the haemoglobin rose in twelve days from 30 per cent. to 70 per cent.

248. Iodine Dosage in Exophthalmic Goitre.

W. O. THOMPSON, A. G. BRAILEY, and PHEBE K. THOMPSON (*Journ. Amer. Med. Assoc.*, December 1st, 1928, p. 1719) have endeavoured to determine the effective range of iodine dosage in exophthalmic goitre. In a study of twenty-five cases it was found that as great a reduction in basal metabolism was obtained by the daily administration of one drop of compound solution of iodine (6.3 mg. of iodine) in twelve cases, and of half a drop (3 mg. of iodine) in eight cases, as with higher doses. The minimum dose that will produce a maximum reduction in basal metabolism has not yet been definitely determined, but this probably lies between one-fifth and one drop of compound solution of iodine (1.3 and 6.3 mg. of iodine). These observations suggest that the minimum dose is a little less for patients at rest in bed than for those who are up and at work. The authors add that when it is considered that one drop of the compound solution contains about twenty-four times the amount of iodine computed by Plummer to be destroyed in the form of thyroxin daily, these results are not surprising.

249. Yatren and Emetine in Colitis.

ACCORDING to L. F. BOUROVA (*Meditzinskaya Misl Usbequistana*, November, 1928, p. 14) the combination of yatren and emetine in amoebic and ulcerative colitis is more effective than emetine alone. Using both drugs together the results were favourable in 96 per cent., as compared with 35 per cent. when emetine alone was administered. In amoebic colitis the results were equally good, both with emetine alone and with the addition of yatren, which was given by the mouth in doses of 0.5 gram three times daily, or in enemata (2 per cent. solution in 200 c.cm. for one enema) during eight to ten days, followed by eight days' rest. The treatment is repeated one to three times if necessary.

Anaesthetics.

250. A Controllable Spinal Anaesthetic.

N. H. GOSSE (*Canadian Med. Assoc. Journ.*, January, 1929, p. 29) advocates the use of a spinal anaesthetic termed "spinocain," which was first introduced by G. P. Pitkin. The preparation contains novocain and strychnine sulphate in a solvent of gliadin and alcohol with normal saline solution in a 2 c.cm. ampoule. A second ampoule of 1 c.cm. capacity, containing ephedrine hydrochloride 5 per cent. and novocain 1 per cent., is used as a preliminary to the spinocain injection to anaesthetize the track of the spinal needle and to prevent any fall in blood pressure which might otherwise result from introducing novocain into the spinal canal. The strychnine is considered to act as a direct stimulant to the vaso-constrictors, to inhibit the action of the anaesthetized nerves, and to stimulate those unaffected. The alcohol, by rendering the anaesthetic fluid of lower specific gravity than that of the spinal fluid, associated with the increased viscosity produced by the gliadin, is thought to assist in the better control of the anaesthesia. As to dosage, Gosse believes that it is rarely necessary to exceed 100 mg. per 150 lb. of body weight. He considers the solution to be the best for spinal anaesthesia and worthy of a wider application.

251. G. P. PITKIN (*Amer. Journ. of Surg.*, December, 1928, p. 537) defines the ideal spinal anaesthetic as one which is certain in effect and constant in duration; has an intensity in direct proportion to the amount injected; does not affect the heart action, arterial pressure, or respiratory function; lessens nausea and vomiting; and abolishes pallor, cold sweats, anxiety, and after-effects. As a result of experience in 11,000 cases, he claims that spinocain has been found to be most satisfactory in producing controllable spinal anaesthesia; it is said to induce a sure, well-defined sacral anaesthesia within three minutes in every case. The equipment for its use is not expensive, and the surgeon may be his own anaesthetist. Controllable spinal anaesthesia is indicated in all cases of tuberculosis, asthma, chest conditions, and for diabetic or nephritic patients to whom inhalation anaesthesia may be harmful or even fatal. Acute abdominal conditions respond well to spinal anaesthesia, as the sphincters are relaxed, peristalsis is increased, acidosis lessened, and distension or ileus less likely to appear. The spinal puncture and injection of spinocain should be conducted with the patient lying on the side; the knees are flexed upon the abdomen, the head is bent forward, and the back is bowed out. The skin over a wide area extending from the fifth or sixth dorsal vertebra to the sacrum is painted with a 3/5 per cent. tincture of iodine. By palpating along the lumbar spine from the twelfth dorsal to the sacrum a wide interspace is found which is the point chosen for puncture; this must be made at right angles to the long axis of the spine and the needle must enter the dura, when the spinal fluid should flow through it. The injection of the anaesthetic solution must not be made until clear spinal fluid flows through the needle, as this is the only assurance that its point is inside the dural sac, and, unless the solution is injected into the subarachnoid space, anaesthesia will not occur. For anaesthesia of the perineal region only 1 c.cm. of spinocain is required, with the patient in a Trendelenburg position of 15 to 18 degrees. For anaesthesia of the legs 2 c.cm. is used, with the table in a Trendelenburg position of 10 to 15 degrees. For anaesthesia to the umbilicus, 2 c.cm. is sufficient for short operations, with the patient in a 7 to 10 degrees Trendelenburg position.

252. Post-operative Acidosis.

V. RAFFO and U. VALLEBONA (*Arch. Ital. di Chir.*, November, 1928, p. 529) publish the results of an examination of 43 patients suffering from various diseases, with reference to post-operative acidosis. The acid-base equilibrium after surgical intervention tends towards ketosis, acidosis, or a combination of these. Ketosis may be partly due to fasting, insufficient oxidation (hepatic insufficiency, morphine, asphyxia), deficient elimination, fat embolism, or faecal stasis. The factors tending to produce acidosis are vomiting, diarrhoea, haemorrhage, nervous reflex, toxic action of the anaesthetic, insufficient pulmonary elimination, fasting, dehydration, purgatives, oliguria, disturbances of the circulation, or certain drugs (morphine, caffeine, calcium). Factors likely to increase the alkalinity of the blood are vomiting, diarrhoea, haemorrhage, and increased irritability of the respiratory centre. The high figures of the alkaline reserve are often only the expression of a special form of acidosis. Post-operative acidosis may pass unobserved in the clinic and only be revealed in the laboratory. The various symptoms attributed to acidosis or ketosis are not pathognomonic, and often fail in well-marked cases of acidosis.

253. **Death from Spinal Anaesthesia.**

E. A. RYGH and D. H. BESSESEN (*Minnesota Med.*, November, 1928, p. 744), considering the causes of death from spinal anaesthesia, state that, while prior to ten years ago the mortality compared unfavourably with that from general inhalation anaesthesia, there are indications to-day that, owing to improved methods as regards drugs and dosage, spinal anaesthesia will eventually supplant other anaesthetics for operations below the diaphragm. The principal causes of death are the action of the drug upon the respiratory system and upon the vasomotor centres, the former following phrenic paralysis through the third, fourth, and fifth cervical nerve roots, or the effect upon the respiratory centre from access of the drug to the fourth ventricle, while the latter results from anaemia of the respiratory centre, due to vasomotor paralysis through the splanchnic nerves with reduction in blood pressure. Vasomotor disturbances can be readily detected by estimating the blood pressure every few minutes for the first ten minutes following injection; preparation is made to give adrenaline and saline injections at once if the blood pressure falls below 100 mm. Important factors in controlling the level of anaesthesia are the specific gravity and diffusibility of the solution used and the position of the patient; by securing accuracy in dosage and employing non-toxic drugs with the addition of adrenaline or ephedrine, and watching the blood pressure, a fatal issue from respiratory or vasomotor paralysis is rendered practically impossible. Patients suitable for spinal anaesthesia are those with surgical lesions below the level of the diaphragm in whom the Trendelenburg position is not contraindicated and in whom there is no hypotension, consideration of the blood pressure being most important.

Obstetrics and Gynaecology.

254. **Rapid Termination of Pregnancy.**

RAPID delivery by manual dilatation of the cervix under spinal anaesthesia has recently been recommended by Delmas as a reliable and safe procedure in cases of accouchement forcé and others (see *Epitome*, November 10th, 1923, para. 375). LE LORIER (*Bull. Soc. d'Obstet. et de Gynécol. de Paris*, December, 1928, p. 903) has tried Delmas's method in seven cases—one of uterine inertia, two of death of the foetus and ruptured membranes, one of foeto-pelvic disproportion, one of neglected shoulder presentation, and one of painful hypertonic uterus in a patient in whom ligamentopexy had been performed. In three cases the os had not begun to dilate; in three cases forceps delivery was used, and in three internal version was effected. In all, manual dilatation of the os was secured with facility and speed, and perineal tears, if noted, were minimal. As against the operation, however, it is noted that in all but one instance cervical tears (falling short of the vaginal vault) occurred; that in one case intrauterine manœuvres were impeded by the contraction ring; and that one patient exhibited uterine atony, with copious and fatal haemorrhages, two hours after labour. According to M. METZGER (*ibid.*, p. 911), who reports five cases of manual dilatation of the cervix under spinal anaesthesia (dystocia being present), dilatation of the os and relaxation of the perineum are readily obtained as a rule, but hypertonia of the uterus may lead to difficulties in forceps application, internal version, or embryotomy. One patient died on the fourth day from the effects of a sudden haemorrhage (cephalotripsy had been performed although the os was not completely dilated); another had a considerable metrostaxis on the fifth day. V. CATHALA (*ibid.*, p. 915) concludes that while dilatation of the cervix under spinal anaesthesia may have limited indications where accouchement forcé is required, it is by no means sufficiently free from danger to be employed as a means of painless delivery, at a selected time, in patients in whom uncomplicated labour is to be expected.

255. **Treatment of Cervical Cancer.**

F. DELPORTE and JEAN CAHEN (*Le Cancer*, No. 4, 1928, p. 289) describe the results of treatment of cases of epithelioma of the uterine cervix for six years. They suggest that research is required on the lines of making the cells of the neoplasm more susceptible to the influence of radiotherapy by increasing their sensitivity. They prefer treatment by radium to surgical methods, and give details which may be summarized as follows. When possible radium tubes are placed round the cervix, and when this can be dilated without risk of sepsis they are introduced within the uterus, but it is often found advisable to delay the intracervical treatment until the tumour has grown smaller and a better view can be obtained. This stage lasts for about twelve days, and results in cures lasting at least five years in 50 per cent. of both operable and inoperable cases. If, however, there is invasion of the uterine adnexa, intra-abdominal treatment is undertaken about six weeks later. Through a central incision below the umbilicus the uterus is examined and three or four needles are placed in suitable positions round it, the anterior and posterior surfaces of the uterus and broad ligaments being packed by gauze to protect the bladder and rectum. The wound is sutured in three layers, except for about one inch, through which the gauze and threads attached to the needles appear. The needles and anterior portion of the gauze are withdrawn after about a week, and the gauze in the pouch of Douglas is removed on the twelfth day. The authors claim a considerably higher proportion of cures in their cases treated by these methods than follow the use of deep radiotherapy. Detailed tables are given of the results obtained, and the percentage of cures is stated as 44 to 54 in operable cases, 25 to 35 in inoperable cases, 10 to 13 in the very advanced stages, and 13 to 18 in patients with recurrences.

256. **Abortifacient Poisoning.**

ACCORDING to N. CANDELA (*Ann. di Ostet. e Ginecol.*, December, 1928, p. 1511) about one-half of criminal abortions follow the ingestion of capsules of apiol. The symptoms of poisoning by this drug show no fundamental difference from those due to the other chemical abortifacients, such as quinine and ergot. Abortion is not secured with certainty even in cases in which the poison proves lethal, and individual variations in susceptibility are well marked. In six cases of poisoning by apiol taken as an ecbolic Candela noted, as the most common findings, pharyngeal necrosis, cloudy swelling of the liver, intense visceral congestion, and intestinal perforation. Renal symptoms included haematuria, nephritis, and uraemia. It is probable that many cases of toxic abortion following ingestion of apiol are wrongly regarded as due to toxic sequels of mechanical injury of the genital organs. From both the therapeutic and medico-legal points of view the detection of apiol poisoning in combination with induced abortion is of importance, and by tests in guinea-pigs Candela has satisfied himself that toxic doses of apiol are associated with the appearance of the drug in the urine, where it can best be detected by making the urine alkaline, extracting by gentle shaking with ether, and adding to the washed concentrated ethereal extract some pure sulphuric acid, when a rosy purple coloration is produced.

257. **Sterility.**

C. MAZER and J. HOFFMAN (*Med. Journ. and Record*, January 16th, 1929, p. 90), from an analysis of 500 cases in the gynaecological department of the Mount Sinai Hospital of Philadelphia, consider that as a preliminary to treating sterility in women the fertility of the male must be definitely established. The male is primarily responsible in about 25 per cent. of the cases and indirectly for most of the infections resulting in female sterility—as, for example, gonorrhoeal endocervicitis and salpingitis; and lacerations of the cervix with subsequent infection play an important part. By means of the Rubin test of transuterine insufflation, or of utero-salpingography with lipiodol, the patency of the Fallopian tubes can be determined; the freeing of adhesions, straightening of tortuosities, dislodging of inspissated mucus, and the opening up of a passage afford a rational method of treatment and diagnosis in some cases. The authors point out that one out of every seven marriage unions in America remains barren, and that the incidence of non-patency and stenosis of the Fallopian tubes in sterile women is about 33 per cent. Endocrine dysfunction from puberty with undeveloped genital organs was present in about 14 per cent. of the cases, while such dysfunction of later development occurred in about 4 per cent. Uterine fibroids, malpositions, and ovarian cysts were only occasionally responsible for sterility. In most of the cases of relative sterility foci of infection were the apparent cause of repeated abortions and prematurity, while syphilis was responsible only in six. In one-fifth of the patients no apparent cause of sterility could be found, and one-third of these eventually bore viable children without any definite treatment having been adopted.

258. **Myomectomy during Pregnancy.**

ACCORDING to S. LIEBMANN (*Zentralbl. f. Gynäk.*, January 19th, 1929, p. 172) conservative operations for myoma during pregnancy can be recommended with confidence; if adequate care is given to the wound in the uterus the pregnancy will probably continue, and dangerous complications are unlikely to occur either during or after labour. Liebmann describes six cases of enucleation of large myomata during pregnancy: one was followed by abortion, five went on to term or nearly to it; four patients had living spontaneously born children, and one could not be traced beyond term. In the first case, that of a nullipara aged 34, married for fifteen years, a subserous myoma filling the true and false pelvis was removed

during the fourth month. In the second case, a myoma reaching above the navel was enucleated during the third month in a nullipara aged 32. In the third case the tumour occupied the pouch of Douglas, and in the fourth an intramural node the size of the fist was extirpated during the third month. The fifth case was that of a nullipara, aged 41, who during the sixth month was found to have a subserous myoma the size of a goose's egg, and subsequently had abdominal pain, pyrexia with rigors, pyuria, and jaundice. The appearance of signs of peritonitis led to a diagnosis of acute purulent cholecystitis, but at operation the acute signs and symptoms were found to be due to infection of the myoma from adhesions to the small intestine and transverse colon. The tumour was removed and drainage was arranged. Six weeks later a living child was expelled spontaneously; the patient recovered after a post-partum attack of pyelitis, followed by bilateral crural thrombosis and metastatic tonsillitis. In the sixth case the myoma, removed during the third month of pregnancy, was necrobiotic.

Pathology.

259. The Virus of Post-vaccinial Encephalitis.

E. BERGER (*Centralbl. f. Bakt.*, January 24th, 1929, p. 138) inoculated the corneas of twelve rabbits with quantities of calf lymph in doses ranging from 0.05 to 0.1 c.cm. The animals were killed at intervals and the brain was examined for the presence of the vaccinia virus. The technique employed was the enrichment method of Ohtawara—namely, the simultaneous inoculation of the brain suspension on to the cornea and into the testicle of normal rabbits. In four out of the twelve rabbits the virus was demonstrated in the brain; these were examined between the fourth and the sixth day after inoculation. There was no evidence of the production of a vaccinial encephalitis, and from the fact that the virus was demonstrable only when the enrichment method was used—simple corneal inoculation giving uniformly negative results—he concludes that it was present in small amount only. In further experiments rabbits which had received corneal inoculations with vaccine lymph were anaesthetized with a chloroform-ether mixture for ten minutes at a time on the second, third, and fifth days after inoculation. No evidence was obtained that this treatment was able to activate the virus in the brain, nor was this brought about by inflicting mechanical injury to the skull. Since many workers believe that post-vaccinial encephalitis is due to the activation of some other virus lying latent in the body, the author made experiments to ascertain whether it was possible to produce an encephalitis, in rabbits chronically infected with herpes, by the inoculation of vaccinia virus. Four rabbits which had survived the corneal inoculation of herpes virus were inoculated two or three weeks later with vaccinia virus, the inoculation being made on to both corneae. All the animals developed keratitis, but none of them showed any symptoms of encephalitis. This attempt to activate the herpes virus—a virus which is known to produce encephalitis in rabbits—resulted in failure.

260. The Thymus and the Healing of Fractures.

O. BARTOLI (*La Chir. degli Organi di Movimento*, December, 1928, p. 168) produced simple fractures of the radius in twenty-four rabbits; he injected one series of six with extract of rabbit thymus; another series received similar injections of extract of calf thymus; in a third series of six the thymus was removed; the fourth (control) series had no treatment. The injections were commenced two or three days after making the fracture, 1 c.cm. of the extract being injected every day until the animal was killed. The animals were killed respectively on the tenth, twentieth, thirtieth, forty-fifth, sixtieth, and seventy-fifth days after the fracture; the progress of healing was noted during life by *x*-ray examinations, and after death by making sections. The results are expressed in tabular form, and indicate that in the group of rabbits which received the homologous extract there was complete ossification and re-establishment of the medullary canal by the thirtieth day, whereas in the control untreated rabbits at this date the callus was cartilaginous, showing only an initial zone of ossification. In group 2, which had received heterologous extract, there was a cartilaginous callus partly ossified; in the animals from which the thymus had been removed the callus was osteoid. At the seventy-fifth day those which had received homologous extract showed only a trace of residual callus, whereas with the untreated, though the callus was completely ossified, the absorption of callus was only commencing. Those rabbits which had received heterologous thymus still had a big callus; in those from which the thymus gland had been removed the callus was osteoid, showing a few calcified trabeculae.

261. Cholesterinaemia in Diphtheria.

P. LEREBOULLET, M. DAVID, and DONATO (*Arch. de Méd. d'Enf.*, December, 1928, p. 703), who record eight illustrative cases in children aged from 2½ to 12 years, made more than 500 estimates of cholesterin in the blood serum of diphtheria patients by Grigaut's colorimetric method, with the following results. In malignant attacks during the first three or four days of the disease the cholesterin content of the blood is lowered to 75 per cent., increased in 20 per cent., and normal in 5 per cent. During the next ten days there is almost always a lower value than during the first four days, and in rapidly fatal cases the fall is quick and considerable. The hypocholesterinaemia is usually accompanied by a similar fall of the glucose content of the blood. After the fifteenth day the degree of cholesterinaemia is variable. In prolonged forms which remain severe and often prove fatal hypocholesterinaemia persists, but in cases which end in recovery there is a progressive rise in the cholesterinaemia. In moderate attacks the cholesterinaemia remains normal or is slightly lowered. In cases which run a favourable course from the first, or which have received large doses of serum on the first day accompanied by subcutaneous injection of suprarenal extract, hypercholesterinaemia may be found. In laryngeal diphtheria the variations in the cholesterinaemia correspond to the degree of diphtherial intoxication. Intercurrent disorders, such as eruptive fevers, broncho-pneumonia, otitis, and suppuration, always cause a fall in cholesterinaemia. Serum sickness, especially when pronounced, always gives rise to hypocholesterinaemia. In diphtherial paralysis, on the other hand, hypercholesterinaemia appears to be very frequent. Injections of cholesterin oil in doses of 1.50 or 3 grams per mille, either alone or in association with suprarenal extract, are followed by encouraging, though inconstant, results.

262. Streptococci in Spinal Fluid in Acute Poliomyelitis.

E. C. ROSENOW (*Journ. Amer. Med. Assoc.*, November 24th, 1928, p. 1594) found Gram-positive diplococci of varying size and shape, arranged singly in short chains, or in small clumps, in the sediment of the spinal fluid of eighteen cases of epidemic poliomyelitis. These organisms were also found in the spinal fluid of three monkeys in which typical poliomyelitis developed after intracerebral inoculation of emulsions of glycerolated brain and cord from three fatal human cases. The cell counts ranged from 15 to 1,270 for each cubic millimetre of spinal fluid in the different cases. The organism was found in the preparalytic stage as early as twelve hours after the onset, and after the paralysis had begun as late as the fourth day of disease. Control smears were made of the spinal fluids from twenty-four other cases of disease of the central nervous system, but in none of these were diplococci demonstrable in smears or on culture. Great difficulty was encountered in cultivation of the organisms from the spinal fluid. All primary cultures in ordinary media proved negative, but growth was obtained in fifteen of the eighteen cases when the spinal fluid or the sediment only was inoculated into a concentrated autoclaved alkaline extract of yeast. The freshly isolated strains of streptococci like those obtained in previous epidemics produced flaccid paralysis in rabbits. The organisms were agglutinated by hyper-immune poliomyelitis antistreptococcal serum.

263. Metabolism of Undernourished Children.

C. C. WANG, JEAN E. HAWKS, and MILDRED KAUCHER (*Amer. Journ. Dis. Child.*, December, 1928, p. 1161) have tried to determine the possible relationship between the nitrogen intake and the rate of growth in normal and undernourished children. They investigated eight normal and nine undernourished children whose ages ranged from 4 to 12 years, the first being on a high protein diet of 4 grams of protein per kilogram of body weight, and the second on a low protein diet of half that protein value. The diets were of equal calorie value. Except, however, in a group of eight children who figured in both experiments the calorie intake and the nitrogen intake varied considerably in different children. The percentage utilization of the calories in a person on the high protein low protein diet was greater than in one on the high protein diet, owing to the higher coefficient of digestibility of the food mixture of the low protein diet. Underweight children seemed to utilize the nitrogen of a low protein diet more efficiently than did normal children. A striking gain in weight followed an increase of the protein in the diet, even in normal children; this was especially marked in undernourished children. The authors advise a diet containing 4 grams of protein per kilogram of body weight for undernourished children, and recommend that the diet of all children, normal or underweight, should contain one quart of milk, for its calcium and vitamin content as well as for its protein content.

PREGNANCY—
ITS DISCOMFORTS

Intolerance of Milk, Indigestion, Flatulence, Constipation, Nausea

SUNSHINE GLAXO with its extra and added Sunshine Vitamin D provides the expectant mother with that extra nourishment she needs, without causing her biliousness, sickness, indigestion, or constipation.

"THE NURSE suggested she should take Sunshine Glaxo last thing at night and twice during the day between meals. Very soon there was a gain in health, constipation disappeared, indigestion was overcome, and the feeling of nausea vanished."

SUNSHINE GLAXO is delicious, soothing, more easily digested than cow's milk, and provides good quality milk on baby's arrival.

ESTABLISHED 1793.

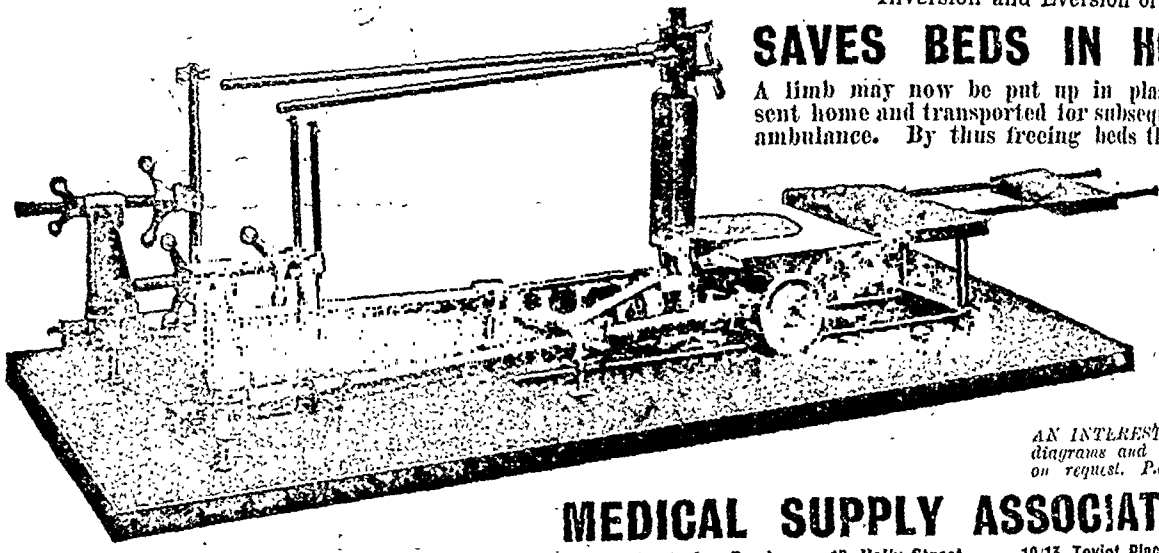
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 32 in. x 11 in. x 7 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, *thus relieving head noises.*
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.*

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

MR R.H.DENT'S
ARDENTE
FOR DEAF EARS

Gas Fires ventilate rooms

There are no fumes from the gas fire. There are products of combustion, of course, as there are from *any living flame.* But they immediately pass up the chimney or flue. And as they rise they cause a gentle upward flow of used air from the room—a system of ventilation more perfect even than that of the open window. That's why—as our scientists have proved—every room should have a chimney or flue reaching up to the roof . . . every room an open fire. . . . The modern *gas fire* which has living flames, gives radiant heat, ceaseless ventilation, and makes no smoke or dirt, is the ideal open fire.

* * *

The B.C.G.A. . . . representing the British Gas Industry, is at the service of the public, without charge, for information and advice on any use of gas. *Mr. G. A. Serviss will welcome enquiries sent to him at the address below.*

4 big advantages

DONIGER Krome-Plate Surgical Instruments possess four big advantages over ordinary nickel-plated instruments. They are:

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

These are facts that have been proved under practical conditions in many important hospitals and clinics in America where Doniger Instruments are used consistently.

Doniger Instruments are made from high carbon steel specially polished to ensure perfect smoothness, then nickel-plated, and finally given a generous coating of chromium. Despite the high quality of the materials and craftsmanship employed, Doniger Instruments cost only a fraction more than nickel-plated instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and [illegible] to the Hospital from the farm, gardens, and orchards of Moulton Park. [illegible] is a feature of this branch, and patients are given every facility to [illegible] in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No. 56 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. CORNISH RIVIERA.—In a small but rapidly growing town (pop. 5,000—6,000) on the Coast, an old-estab. PRACTICE producing last year over £1,000, including appts. and panel of 550 to 600. Opposition weak. Delightful residence, standing in own grounds of 1¼ acres (croquet and tennis lawns, etc.) and eminently suitable for Resident Patients, which Vendor has been in the habit of taking. Contains professional rooms, 4 reception, 9 bedrooms, 2 bathrooms, etc. Water and electric light. Garage. Price for freehold £4,000. Prem. £1,500.
2. HOME COUNTIES.—PARTNERSHIP.—A three-eighths share (with increase later) in a very well-established mixed-class Practice, producing about £3,000 p.a. (including panel of 1,500), situated in a desirable residential district. Fees from 3/6 to 21/-. Suitable accommodation available. Ingoing Partner should be between 30 and 35, and preferably hold University degree. Premium 2 years' purchase.
3. LONDON, —A ONE-THIRD SHARE, to commence wit mixed general Practice. Income approxima ppts. and panel of over 3,000. Surgery fe upwards. If unmarried, ingoing Partner could reside with senior; otherwise, suitable house available. Premium 2 years' purchase, *half by arrangement.*
4. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—A half share, with succession to the whole in about two years, in a very old-established non-panel Practice, held by Vendor 26 years. Steady average income of £2,300. Surgery fees 2/6 and 3/6, visits mainly 5/- and 7/6. Very little midwifery. Good house, in main road, with garden. Held on lease, with nearly 15 years to run, at a rental of only £55 p.a. Premium 2 years' purchase. Very good scope for increase.
5. KENT.—*COUNTRY PRACTICE, within six miles of the Coast.*—Old-established mixed general Practice. Income for past twelve months £1,672, including appts. about £60, and panel of over 700. Fees 3/6 to 21/-. *Not much midwifery* 2 to 7 gns. Good house, with 2 reception, 5 bedrooms, etc. Large garden and orchard. Garage for 2 cars. Price for freehold £1,350. Sport of all kinds, and schools within reach. Premium £2,250.
6. PARTNERSHIP.—SOUTH COAST.—In a fashionable watering-place, the two-thirds share is for disposal in a mixed Homœopathic and Allopathic (roughly half and half) good-class non-dispensing, non-panel conection, in which there is a certain amount of surgery, and ingoing partner should be an operating surgeon Receipts average over £3,600 p.a. Fees up to 10/6. Very little midwifery Large and suitable maisonette available, with ample accommodation, in excellent position. Garage. Rent, on lease, £250 p.a. Premium for share 1½ years' purchase.
7. PARTNERSHIP.—Within 3 miles North-West of Charing Cross.—*The half share of an old-established middle and working-class Practice,* averaging about £2,100 p.a., including panel of 1,300. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 bed-rooms, bathroom, kitchen, etc. Small garden. Net rental, on lease, about £60 p.a. Premium 2 years' purchase.
8. HAMPSHIRE.—PARTNERSHIP.—Third share of an old-established *unopposed Country Practice,* in very pretty district within a few miles of a large town, and producing nearly £2,500 p.a., including appointments £130, and panel of 1,520. Visits 5/6 to 21/-. Mids. 2 to 10 gns. Large house (having eight or nine rooms, with garden, etc.), which must be purchased, or ingoing partner could reside in rooms until a smaller one becomes available. Premium 2 years' purchase, half down and balance in 12 or 18 months.
9. KENT.—Old-established Country PRACTICE, situated in very favourite locality within 5 miles of the coast. Income for past 12 months £1,030. Surgery fees 3/6 upwards, visits 5/- to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
10. PEAK DISTRICT.—Old-established mixed general Country PRACTICE, *situated in very delightful district, and offering scope.* Average income about £1,000, including Poor Law appt. and panel of 660. Fees 3/6 to 10/6. Good house, on lease, rent £84 p.a. Excellent *schools within reach. Premium 1¼ years' purchase.*
11. HOME COUNTIES.—GROWING COUNTRY DISTRICT.—Old-established mainly middle and working-class PRACTICE. Income for the last year £550, with ample scope for increase. Fees 2/6 to 7/6. Little midwifery Good freehold house, price £1,500, part on mortgage. Sport of all kinds. Knowledge of refractions advantageous. Premium £850.
12. LONDON, NORTH.—OUTLYING RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share (and up to one-half in two years' time) is offered in an old-established mixed general Practice, averaging about £2,000 p.a., with good scope. Non-panel at present, but ingoing partner should undertake this work. Fees 3/6 to 7/6, a few at 15/-. Little midwifery 3 to 10 gns Suitable house can be bought. Sport of all kinds. Premium 2 years' purchase.
13. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the *immediate* past year £5,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
14. LONDON, S.E. (CROYDON AREA).—Old-established rapidly increasing middle-class PRACTICE. Income for immediate past year over £1,300, including panel of 700. Surgery fees 2/6 to 5/-. Visits 3/6 to 10/6. Thirty midwifery cases yearly from 3 to 10 guineas. Very commodious house on lease, with 11 years to run, rent £70, Premium £2,000.
15. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
16. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—*upper and middle-class.* Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (*which has been valued*) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.

Ex- e, with oak panelling, etc., 2 reception, 10 bedrooms, and professional rooms. Well-stocked garden of 1½ acres, *and 12 acres of grassland. Recently re-decorated throughout.* Electric light. Price for freehold £4,500, of which £2,200 could remain on mortgage. Premium 1½ years' purchase.
22. CHANNEL ISLANDS.—*Old-established general PRACTICE.* Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools Price for practice and house £3,000.
23. WEST OF ENGLAND.—Very easily worked unopposed Country PRACTICE. *Gross cash receipts for immediate past 12 months £657,* including panel of 500. Fees from 2/6 to 12/6. Midwifery 3 to 5 gns. Nice house, with 2 reception, 6 bedrooms, etc., professional rooms. Large garden and paddock. Price for freehold £1,200. Premium 1½ years' purchase.
24. LANCS.—In a rapidly growing good-class suburb of large town (pop. nearly 200,000), a very old-estab. PRACTICE, held by Vendor over 30 years, and averaging about £900 p.a., including Union (£80, with prospect of increase shortly) and panel of nearly 1,000. There is a surgery in centre of town to which bulk of practice and panel work is attached. Private residence contains 2 reception, 3 bedrooms, bathroom, etc., and small garden. Both Vendor's properties. Price £1,750, £900 on mortgage, or would be rented. Prem. 1½ yrs.' pur.

REQUIRED.—MEDICAL OFFICER for Cable Company. Salary £500 p.a., all found. Three years' engagement. First-class out and home. Must be of British nationality and under 30 years of age. Sail end of March. Personal application preferred.

Full Schedule of Terms and Conditions will be forwarded on application.

Valentine's Meat-Juice

In the **Gastric Form of Influenza** and its **Debility,** in **Typhoid** and **Acute Pneumonia,** in the **Exhaustion** of **Phthisis** and **Pulmonary Diseases, Valentine's Meat-Juice Sustains** and **Strengthens**

When Other Food Fails

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

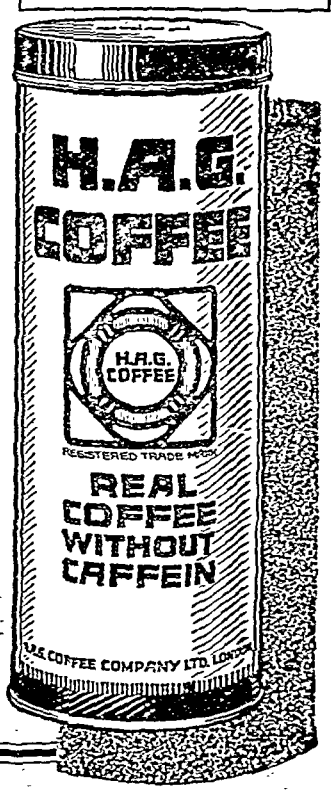
THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance



H.A.G. COFFEE CO. LTD.

40 Theobald's Road, London, W.C.1

AMENORRHEA
DYSMENORRHEA

"It is a very great mistake to treat amenorrhea as though it were simply a lack of the catamenia, for it is a great deal more than that. Behind this lack lies a cause. It may be in the uterus or the ovaries, or it may be still farther back in the secretions of the endocrine glands or in the functioning of the vegetative nervous system."—("The Treatment of Amenorrhea," Dalché, *Revue Française de Gynecologie et d'Obstetrique*, May 1, 1920.)

In the treatment of irregularities of the catamenia, rational therapeutic procedure is directed to the restoration of normal balance in the endocrine and vegetative nervous systems.

Hormotone
BRAND

contains thyroid, pituitary, adrenal, and gonad substance, combined to take advantage of the demonstrated synergism existing between them. In the treatment of these disorders Hormotone has been very successful.

Dose: One or two tablets three times daily.

BELLED MIRROR OF ANCIENT JAPANESE MANUFACTURE. THE MIRROR, STILL AN OBJECT OF RELIGIOUS HONOURS, WAS A VERY SACRED EMBLEM TO THE ANCIENT JAPANESE.—The mirror, symbol of the sun and concrete token of the presence of the sun-goddess, figures largely in Japanese myths. In one of these the sun-goddess gives the mirror to her grandchild, Ninigi, in sending him down to be the ruler of the world; she tells him to look upon it as her emblem or even as her actual self. The mirror was considered, also, to be the symbol of virtue and was buried with the dead as an amulet against decay. An especially sacred mirror mentioned in the Chronicles of Japan under the date 92 B.C. was an object of worship at that time; it was, later, enshrined at Ise, where it is still preserved with the greatest veneration. Sun-worship was the central feature of the early religion of Japan. Shinto, "the way of the gods" is, however, now almost extinct. Nevertheless, it served to give a religious quality to some of the principles which have led to stability in the state, e.g., to the idea of reverence for the Mikado.

It must be understood that the acceptance by the British Medical Association of an Advertisement does not imply a recommendation, and that no responsibility is accepted with regard to the accuracy of the statements therein contained.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

J. & A. CHURCHILL

SEVENTH EDITION. 2 Vols. 900 Illustrations (43 in Colour). 70s., postage 1s. 3d.

ROWLANDS & TURNER'S OPERATIONS OF SURGERY

"This is probably the most important modern textbook on Operative Surgery published by British Surgeons. "The volumes are not only safe as a book of reference, but of the greatest value to the general surgeon. The searching and detailed revision which has been carried out in the last edition does great credit to the ability and industry of the authors."—PRACTITIONER.

With 13 Coloured Plates and 49 Text-figures. 15s., postage 9d.

RADIUM TREATMENT OF CANCER

By STANFORD CADE, F.R.C.S.,

Assistant Surgeon, Joint Lecturer on Surgery and Teacher of Practical Surgery, Westminster Hospital.

"... a technical work, such as Mr Cade's, will prove of inestimable value, and we cannot recommend too strongly that every surgeon who has hitherto not had the opportunity to employ radium should read this volume very carefully."—BRIT. MED. JOURN.

24 Illustrations. 8s. 6d., postage 6d.

SURGICAL RADIOLOGY

By A. P. BERTWISTLE, M.B., Ch.B., F.R.C.S.Ed., late Resident Surgical Officer, General Infirmary, Leeds. With Introduction by D. P. D. WILKIE, O.B.E., F.R.C.S., Professor of Surgery, University of Edinburgh.

Illustrated. 12s. 6d., postage 6d.

METHODS AND USES OF

HYPNOSIS AND SELF-HYPNOSIS.

By Bernard Hollander, M.D. 6s.

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as detailed evidence of phenomena throwing light on the mysteries of thought-transference, clairvoyance, etc.

GEO. ALLEN & UNWIN, Museum Street, London, W.C.1.

A Surgical Work kept perpetually up-to-date

This valuable work is offered you for FREE Perusal.

A disadvantage of ordinary surgical literature is that even the finest work becomes out-of-date.

A "living" book has been devised to meet this serious difficulty. In Nelson's "Loose-Leaf Surgery" the plan has been adopted of writing a work which is an epitome of the very latest world knowledge and practice of surgery. Then by means of loose leaves supplied periodically the book is kept constantly up-to-date. It should be noted that the obsolete information is not left in the book, but articles are reviewed and revised in the light of the very latest findings and often whole pages, or it may be articles, completely rewritten, and the subscriber advised to replace the old pages with new ones which are sent to him. Every surgeon will realise that this revision work, being conscientiously and skilfully done, makes Nelson's "Loose-Leaf Living Surgery" a book which stands by itself in usefulness.

The work emanates from the American branch of the well-known Scottish House of Nelson, and no effort or expense has been spared to make the body of the book a classic. Whilst the American influence is obvious, yet our own A. J. Walton, Putti of Bologna, Gaston Labat of Montpelier University, and Thorkild Rovsing of Copenhagen are amongst the European contributors.

The Volumes are divided as to main subjects:

Vol. 1: Pathology, Technic, Legal Relations, etc. Vol. 2: Head and Neck, Tuberculosis, Diabetes, Nervous System, etc. Vol. 3: Chiefly Orthopædic. Vol. 4: Heart, Breast and Lungs, etc. Vol. 5: Abdominal. Vol. 6: Urology. Vol. 7: Gynecology. There are thousands of illustrations of a strikingly clear and informative character in the present 5,000 pages.

If you are interested it will be a pleasure to send you any one or more of the books (even the complete set) to look over without asking you to assume the slightest obligation to purchase. There will be included a complete analysis of contents of the seven volumes.

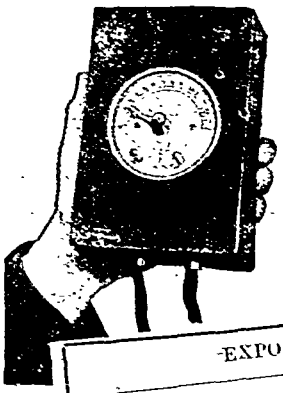
Without previous experience— you can make your own Radiograms!



THERE are uses for X-rays in almost every practice. No longer need the medical man be without. The "METALIX-PORTABLE" is within the reach of every practitioner, and successful radiograms can be taken without fuss or bother. Nor are the advantages of X-ray diagnosis confined to the consulting room alone. Wherever there is electric light—there you can use the "METALIX-PORTABLE."

EXPOSURE TABLE.

Subject.	Intensifying Screens.	
	None.	Two Screens.
Hand	2 secs.	—
Elbow	3 ,,	—
Foot	4 ,,	1 sec.
Tibia	5 ,,	1 ,,
Shoulder Joint	9 ,,	1½ secs.
Cervical Vertebræ ...	9 ,,	1½ ,,
Knee Joint	—	1½ ,,
Skull (lateral)	—	6 ,,
Hip and Pelvis	—	6 ,,
Chest	—	1 ,,
Teeth (extra-oral) ...	—	3 secs.
Teeth (intra-oral) ...	1 sec.	—

When not in use the "METALIX-PORTABLE" stows away to form two convenient packages. The work of erection takes only two minutes, whilst the control is of the simplest possible form.

There are no dangers due to exposure to unwanted radiation, and whilst in operation the apparatus is absolutely shockproof. A postcard will bring you full particulars, or we will gladly arrange a demonstration.

Made by

CARR'S of Carlisle

Prescribed in numerous cases

of

nervous and heart disorders, also rheumatic conditions, etc.

The active substances of the extracts from cone bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Affords relief in all cases of high blood pressure

The daily exhibition of Sal Hepatica, the non-habit forming saline purgative, has proved of extreme benefit in all cases of high blood pressure. ¶ Sal Hepatica is also recommended as a rapid means of relieving the stress in cases of dysmenorrhœa. One or two drachms administered on the morning before the expected period, and again at its outset, rarely fails to relieve both the pain and depression. ¶ In chronic constipation the regular exhibition of Sal Hepatica for a week or two restores the daily habit of defecation. ¶ Sal Hepatica is not a "patent medicine" and is only advertised to the medical profession.

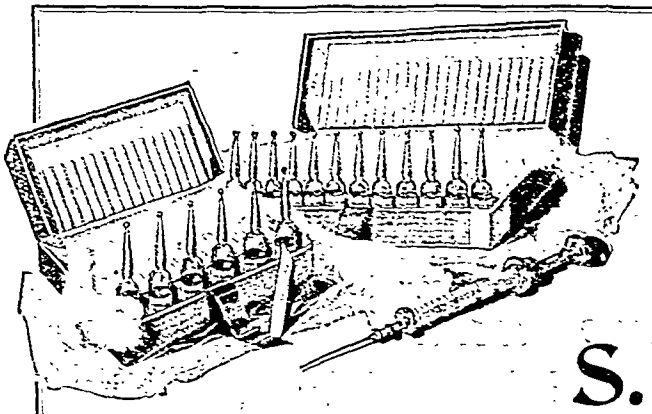
Sal Hepatica

the proved medical saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to

BRISTOL-MYERS COMPANY, 112, Cheapside, London, E.C.2



S.U.P. 36

Intramuscular injections of S.U.P. 36 are of considerable value in practically every inflammatory condition where there is a rise of temperature.

Literature and clinical reports on request

In the treatment of colds, influenza and pneumonia some remarkable results have been achieved; cases are on record where single injections have been given in the acute stages of influenza and the patients were able to resume work within two days.

Vapo-Cresolene
Est. 1879
Sold by all Chemists

Write for descriptive Booklet No. 67B.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.
This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

Coated Tongue and Toxemia

Coating on the tongue consists of epithelial cells, molds, yeast, and many bacteria, some highly virulent. Normally the saliva prevents growth of the latter. If the resistance of the blood is lowered, the saliva loses its germ-destroying and inhibiting power. A tongue coating appears.

In the constipated colon, putrefactive bacteria produce highly active poisons such as skatol, indol, etc. These enter the blood, lower its resistance, and thus weaken all fluid secretions such as the saliva. No wonder 85 per cent. of all sick people have coated tongues. Constipation is almost universal among the sick.

If the tongue indicates toxemia, prescribe Nujol—the safe and effective treatment. Many intestinal toxins are themselves absorbed by Nujol.

Nujol

REGISTERED TRADE MARK

Once absorbed by Nujol, intestinal toxins cannot be absorbed by the system, as Nujol itself is non-absorbable.

Science once more endorses HOVIS

IRREFUTABLE EVIDENCE

Scientific Research into the essential factors underlying the bread question has brought to light certain facts of the highest practical value to medical men as well as to the general public.

HOVIS is shown, from an analysis of many experiments, not only to possess a larger content of the vital element Vitamin B than other breads, but provides more positive nourishment for the quantity consumed.

One slice of HOVIS weighing 1 oz. contains as much Vitamin as 2 oz. of wholemeal, or 5 to 6 g. of fresh yeast; white bread contains only about 2 per cent. of yeast.

It is also found that "brownness" of bread is no measure of the Vitamin content.

The Wheat Germ the secret of Hovis Nutrition

By blending the finest white flour with 25 per cent. wheat germ, HOVIS combines the goodness of the one with the rich Vitamin B qualities of the other. Further, containing no bran, it is very easily digested.

These facts all point to one conclusion: that in dietetic value HOVIS holds the first place for promoting health.

HOVIS

HOVIS LTD. LONDON & MACCLESFIELD

"In my own wife's Case"

I have used this sample in my own wife's case. She was in a considerably debilitated condition, and there has been a very marked improvement, particularly in the condition of the nervous system, which was the seat of the main trouble. I would like to continue the treatment, and I have been so struck with the results that I am anxious to try it in a case of neurasthenia.

———, M.R.C.S., L.R.C.P., M.B., Ch.B.

NEARLY every day letters are received from Medical men in private practice, in clinics and hospitals, endorsing the value of "NEW-PROMONTA" as a body builder and as a stimulant for depleted nerve tissues.

The beneficial results obtained from "NEW-PROMONTA" are unquestionably due to the skilful retention, in an unchanged condition and in exactly the correct proportions, of Lipoids, Phosphatides, and the essential Vitamins A, B, D, and E. It is apparent, therefore, that "NEW-PROMONTA" forms a remarkably consistent and reliable prescription for the treatment of:

1. All forms of Neurasthenia.
2. Insomnia.
3. Various types of Anæmia.
4. After effects of Influenza.
5. Conditions of Functional insufficiency.
6. In Illness and in Convalescence.

NEW PROMONTA

A SCIENTIFIC FOOD FOR NERVES AND BRAIN

"NEW-PROMONTA" is available in powder form in boxes of ¼ lb. at 3/- and ½ lb. at 5/6, and in tablet form in boxes of 54 tablets at 3/6.

It may be obtained from the leading Chemists and Stores. Free Samples for clinical trials at the disposal of the Medical Profession.

WRIGHT'S LYSOL

BRITISH MADE :: :: BRITISH OWNED

"LYSOL"—Your patients must always qualify the word.

To ask merely for "Lysol" is dangerous, for they may be given an inferior Lysol that will actually do far more harm than good. Tell them, for their own safety, to insist on Wright's Lysol. It gives sure results—always. It is perfectly pure, non-caustic, and causes no irritation. British owned and made under the strict Rideal-Walker control test by the makers of the world-renowned Wright's Coal Tar Soap—Producers of Disinfectants for over sixty years.

Tell your patients to say "Wright's" before saying "Lysol." That way certain safety and protection.

A handy graduated measure is provided with every bottle.

Influenza and Capillary Tone

Another influenza epidemic finds us still without a specific preventive or a specific remedy. Fortunately, both the incidence and the course of the disease can be favourably modified by the observance of such rules as medical experience teaches.

It is essential to maintain vigorous metabolism and healthy capillary tone, whilst avoiding undue cold and damp. Adequate stimulation of the sensory nerve-fibrils of the skin, also, is of supreme importance in keeping the body's resisting power at its highest, and in increasing its recovery-capacity. For these purposes, THERMOGENE has been found by many medical men and their patients to be convenient, cleanly and effective.

Thermogene is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

THERMOGENE
MEDICATED WADDING

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with Thermogene and its many uses in practice.
The Thermogene Co., Ltd., Queen's Road, Hayward's Heath, Sussex.

INSULIN "A.B."

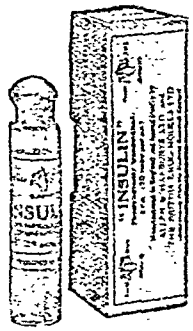
TRADE A B MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.
Packed in bottles containing:
5 c.c. (100 units or 10 doses) 2/8 each
10 c.c. (200 „ 20 „) 5/4 „
25 c.c. (500 „ 50 „) 13/4 „

40 units per c.c.
Packed in bottles containing:
5 c.c. (200 units or 20 doses) 5/4 each

Full particulars and the latest literature will be sent free to members of the Medical Profession.

THE NATURAL MINERAL WATERS OF CARLSBAD

Sprudel, Muhlbrunnen, and Schlossbrunnen

These waters act:

(1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.

(2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of

Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary organs.

Bottled under Official Supervision at Carlsbad and regularly imported by the Sole Agents:

INGRAM & ROYLE, Ltd.,

BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.

And at LIVERPOOL and BRISTOL.

Samples and Descriptive Pamphlet forwarded on application.

Analysis of the Cresylic Acid Content of Lysolats

There is no need to remind Medical Men that the lysols on the market represent varying grades of cresylic acid, many containing a high percentage of impurities which attack and irritate the tissues. For the information of doctors who insist upon the highest grade of cresylic acid, the makers of Lysolats wish to make known the following analysis of the cresylic acid content of their solid form of lysol.

Composition. 99-100 per cent. (A mixture of 50 per. cent. Meta-Cresol, 25 per cent. Para-Cresol, 25 per cent. Ortho-Cresol, with small quantities of Homologues.) Impurities do not exceed 0.1 per cent., including water, as follows:—

Pyridine, 0.05 per cent. maximum.
Naphthalene, 0.05 per cent. „
Light Oil, nil.

Specific Gravity. 1.040 to 1.047 at 15.5° Cent.

Boiling Point. Not less than 90 per cent. distills between 195° and 205° Cent.

Odour. Pleasant. Clean and free from sulphuretted hydrogen.

Solubility in Caustic Soda. 10 c.c. dissolved in 40 c.c. of caustic soda solution (of a specific gravity of 1.060) gives a clear solution.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney Street, London, S.E.1.

Lysolats (LYSOL TABLETS)

PATENTED 1907

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

INFLUENZA

The nasal and oral cavities are the usual route of infection. Mistol applied with a Mistol dropper in the nose is an ideal preventive. Being an oily preparation Mistol diffuses and spreads itself in a thin film over all parts of the mucous membranes of the nose and throat. It clings tenaciously to mucous membranes, and is not easily washed away by the natural secretions. Thus it affords relief in all inflamed and irritated conditions, and assists in warding off infection.

Sold in original sealed cartons containing a—

Mistol
(Registered Trade Mark)

Two-ounce Bottle and Mistol Dropper.

BOOTS PRODUCTS

Specially indicated in
NEPHRITIS—URÆMIA
ECLAMPSIA—ALBUMINURIA
and allied conditions

Prompt and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea. Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated.

They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy.

The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

ALOCOL

Colloidal Hydroxide of Aluminium

Successful Treatment of Hyperchlorhydria

"Alocol" is a triumph of colloidal therapy, because it is completely free from the marked disadvantages associated with the usual alkaline medicaments.

Take bicarbonate of soda as an example. When in the stomach it is transformed into sodium chloride—the very product which goes to the formation of hydrochloric acid. To combat hyperacidity by such means is to create a vicious circle.

Note the different action of "Alocol." It absorbs excess of hydrochloric acid and the acid-containing mass is finally evacuated from the lower bowel. This colloido-chemical absorption removes from the system the causative acid radicle (Cl) instead of merely neutralizing it. "Alocol" thus prevents reabsorption, accumulation, and consequent recurrence of the symptoms of the disease.

"Alocol" leaves intact the acid reaction of the gastric juice and its normal digestive and bactericidal functions. It is the remedy *par excellence* for hyperchlorhydria. The absorbent, healing, and sedative properties of "Alocol" also prove of the greatest value in successful treatment of the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, infective enteritis, etc.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

Intestinal Disinfection

BACILLUS COLI BACILLURIA AND URINARY INFECTIONS

CONDITIONS dependent upon infection of the urinary tract by *B. coli* are by no means uncommon, and present varying degrees of severity, from serious suppurative lesions of the kidney to mild bacilluria of little importance.

The mechanism of infection by *B. coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B. coli* are common in urinary infections in the male).

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed, and those already located in the urinary tract may be attacked by a urinary antiseptic. By the combined administration of Kerol, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B. coli* is placed on a rational basis, and many cases are cured by this line of treatment when they fail to yield to urotropin alone.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

The value of Radio-Malt in the prophylaxis and treatment of many diseases is appreciated by physicians the world over.

Radio-Malt contains Vitamin A, Vitamins B_1 and B_2 and Vitamin D in standardised amounts, and it is prescribed in the prophylaxis and treatment of conditions resulting from deficiencies of these vitamins.

Radio-Malt corrects faulty calcium and phosphorus metabolism, and it promotes healthy growth and normal development of bones and teeth.

Radio-Malt also checks dental caries, prevents intestinal stasis, stimulates the appetite and acts as a general tonic; further, being a definite galactagogue, it is a valuable extra-dietary product for nursing mothers.

HEWLETT'S
ORIGINAL PREPARATIONS.

HORMONIGEN
(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the pluriglandular system, and in anæmia. In Amenorrhœa, Dysmenorrhœa, and at the Menopause, Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE: HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

LIN. BETULÆ CO.
(HEWLETT'S)

Therapeutically equivalent to several times its weight of Sodium Salicylate without causing headache, tinnitus, etc. Has proved most useful in the external treatment of pure Rheumatism, Sciatica, Lumbago, etc. The external dose is about one drachm rubbed over the affected parts.

In 5, 10, 22, 40, and 90-oz Bottles.

PRICE 10/6 PER LB.

MIST. PRUNI VIRG. CONC.
(HEWLETT'S)

A valuable stimulant and expectorant cough mixture, containing Carbonate of Ammonium, Ipecacuanha, Senega, Squill, and Syrup of Wild Cherry Bark. Quite free from Morphine, Opium, or poisons, so can be safely administered to children.

Dose: 1 to 2 drachms diluted.

In 22, 40, and 90-oz. Bottles only.

PRICE 3/3 PER LB.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent. of Iodine, and is, therefore, stronger than the B.P. Ointment, whilst it does not harden or discolour the skin.

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc. Ung. Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis.

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

VERONIGEN
(Formerly known as MIST. VERONAL CO.)
(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, 10/6 PER LB.

MIST. TUSSI RUB. CONC.
(HEWLETT'S)

A favourite and economical cough mixture, [illegible]romic Acid, Chlorodyne, [illegible] Acid, etc. Most successful in allaying post-influenza coughs that are so persistent. One or two ounces diluted with water to make eight ounces forms one of the most effective and elegant mixtures that can be made, and certainly the least expensive.

In 22-oz., 40-oz., 4½-lb., and 8-lb. Bottles only

PRICE 2/9 PER LB.

PUBLIC NOTICE

re

"RYVITA CRISPBREAD"

and

"THE RYVITA CRISPBREAD HABIT"

We acknowledge with much pleasure and grateful thanks the volume of congratulations on our successful introduction of "Ryvita Crispbread" to the British Isles.

When we gave to the British public this new and invaluable food—creating throughout our country the *Ryvita Crispbread habit*—we started what has now become almost a revolution in the bread-eating habit of the nation.

"Ryvita Crispbread" is the successful outcome of generations of experience directed to making just this one thing *right*.

That it is, and does, all that we claim for it is proved by the welcome it has received from Doctors, Dentists, and food experts, who not only prescribe it but have it as the daily bread in their own homes.

Because of its success, not only with the professions and the experts, but with the ordinary folk of these islands, there have arisen a number of "imitation Crispbreads." Some of these are not bad—*as imitations*—some are bad, some quite bad.

We make "Ryvita Crispbread" in Sweden because this type of bread is essentially and characteristically Swedish. The special ovens which we use are a mere item compared with the skill and long experience needed to make Ryvita *right*. It has taken generations of experience devoted exclusively to making just this type of bread to win the present perfection of "Ryvita Crispbread."

Although we make "Ryvita Crispbread" in Sweden, we who own and control the Ryvita Company are British. We buy British when it is best. But, like most other British people, we *will* have the best.

When we smoke a cigar it must be—Havana made in Cuba. After dinner, when we offer our friends a glass of port—it must be port from Portugal. When we have a little party, our champagne must be genuine from France. The suggestion that you should buy imitation Crispbreads merely because they are "British made" is as ludicrous as it would be to claim pre-eminence for British Cigars—British Port—or British Champagne.

Whilst the Ryvita Company is proud of its achievement in popularising the healthful *Ryvita Crispbread habit in this country*, it entirely dissociates itself from these hastily prepared substitutes.

The genuine original "Ryvita Crispbread"—crisp, scrunchy, and delicious . . . the bread of life and health—helps to make indigestion, constipation, malnutrition, and obesity unknown.

"Ryvita Crispbread" is sold by all good grocers and stores at 1/6 per 40–50 slice (1 lb.) carton; ½ lb. carton, 10d.

THE RYVITA COMPANY
409, RYVITA HOUSE
96, SOUTHWARK STREET
LONDON, S.E.1

★ FREE—*A postcard sent to-day will bring you by return a generous free sample of the genuine original "Ryvita Crispbread"*

"RYVITA CRISPBREAD MAKES YOU FIT—AND KEEPS YOU SLIM"

(*Aesculapius*)

WHOOPING COUGH

Reports of the use of Ephedrine in Whooping Cough are extremely encouraging. In 20 cases treated solely with Ephedrine given by the mouth, relief from spasm and vomiting occurred in 18 of the patients. In some a cough remained, but it was of the mild type associated with upper respiratory infection and not characteristic of whooping cough. Ephedrine is specially useful during the second stage.

EVANS' SYRUP OF EPHEDRINE

This is a pleasant and most effective form of medication to control the spasmodic coughing and vomiting of Whooping Cough. It contains Ephedrine Hydrochlor gr. 1/8 in one drachm. The dose is one to two drachms according to age, and it is generally administered night and morning, and occasionally three times a day.

Prices: 4 oz. 3/-; 8 oz. 5/6; 16 oz. 10/6.

Brochure on application to:

Evans' Biological Institute, Runcorn.

Vita-Weat contains every part of the wheat berry

When a diet regime is prescribed it is usual to include Vita-Weat, the British whole-wheat crispbread, in place of soft wholemeal or white bread.

Vita-Weat is an article of diet combining the nutritive and health-giving properties of the best wholemeal bread with the palatability of the white loaf, at the same time ensuring an easily digested product with a high Vitamin, Caloric, and Protein content.

It is an all-British crispbread, guaranteed to be made from 100 per cent. stone-ground whole-wheat grown within the Empire. It is of distinctive texture, inviting mastication and insalivation; it has a delicious "crunchiness" and a pleasing ripe-corn flavour; and it contains every part of the wheat berry, nothing whatever being removed in the process of manufacture.

Not the least of the many benefits to be obtained from a regular diet of Vita-Weat is that of intestinal correction and the prevention of many of the intestinal and gastro-intestinal ailments due to constipation.

When forming a suitable proportion of the daily diet, Vita-Weat acts as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

"STERULES"

(Registered Trade Mark)

FOR

Hypodermic, Intramuscular, Intravenous, and other forms of Injection.

(Care should be taken to prevent confusion as to use in each instance.)

	Box of	
ACID NUCLEINIC (*hypod. and intram.*) *for promoting leucocytosis in acute fevers, pneumonia, etc.* ... ... 5%. 1 c.c.	10	5/6
ARSENIC AND IRON (*hypod. and intram.*), *successful in the treatment of anæmia,* Nos. 1 and 2	„	4/6
Either form with Strych., 1/60 grain ...	„	4/6
BISMUTOL (Sodium-Potassium Bismuthyl Tartrate, *for intramuscular injection in syphilis*	„	5/6
CALCIUM CHLORIDE, *hæmostatic and in calcium therapy.* 1 grain in 1 c.c. and other strengths	„	4/6
CAMPHOR (*hypod.*). ½ grain in Ether 1 c.c.	„	5/6
CHOLINE HCl., 0.6 gm. *in* 6 c.c *for dilution* to 180 c.c. *In ileus*	each	4/6
CURSCHMANN'S CAMPHOR SOLUTION (*hyped., for the treatment of shock* 1 c.c.	Box of 10	5/6
EMETINE HCl. (*hypod., intrav. or intram.*), ¼ and ⅓ grain, 4/6; ¼ gr., 5/6; 1 gr., *In amœbic dysentery, often in conjunction with Auremetine.*		10/0
ENESOL, *see* Hydrarg. Salicyl-arsenate.		
GOLD, COLLOIDAL (*hypod.*), 2 c.c.	5	5/6
1 c.c.	5	7/6
In alcoholism and the Morphine Habit.		
GLUCOSE SOLUTION, *Conc., for producing 2 pints of 5% solution for intravenous feeding*	each	2/6
GUAIACOL, IODINE AND CAMPHOR, *in rheumatoid arthritis* ...	Box of 10	5/6
GUM SOLUTION, *Conc.* (*intrav.*). *for surgical shock*	each	2/6
HYDRARG. INTRAMUSC. Lambkin, 10 m., *in syphilis*	Box of 10	4/6
HYDRARG. SALICYL-ARSENATE (*intram.*). *in syphilis.* 1 grain in 30 min. ...	„	5/6
INDIGO-CARMINE (*intrav.*). *Renal indicator* ... 1%. 5 c.c.. 5/6; 10 c.c.	„	7/6
INJ. CACODYL CO. (*hypod.*) ... 1 c.c.	„	5/6

	Box of	
MANGANESE BUTYRATE (*intram.*). *in furunculosis, boils, etc.,* 1% ... ... 1 c.c.	10	4/6
MANNITOL-QUININE, *the new basic form of Quinine. On clinical trial* ... 2 c.c.	„	5/6
MERCUROME (R.T.M.). *The new non-ionised Mercurial.* 0.3 gm. *for making solutions for vesical injections*	„	5/6
NOVOCAIN, ½ gr., Adrenalin 1/1.000 grain, *as a local anæsthetic*	„	6/6
PEPTONE FOR ASTHMA, *series of* 10 *graded doses, intravenous and in ramus-cular* (*See special leaflet on request*)	„	7/6
PHENOLSULPHONEPHTHALEIN (*subcut.*) 6 mgr., *for Kidney Test* ...	„	7/6
PITUITARY (Infundibular) (*intram.*). made under Licence, ½ c.c., 5/6; 1 c.c.	„	7/6
QUININE-URETHANE, *in varicose veins,* 2 c.c.	„	7/6
SODIUM CACODYLATE, 1 grain *in* Nucleinic Acid Solution 1 c.c., *in Septicæmia*	„	5/6
SODIUM CHAULMOOGRATE "C." *in leprosy,* 2 grain, 5/6 3 grain	„	6/6
SODIUM MORRHUATE (*subcut. and intrav.*), *in tuberculosis and leprosy* 3%. ½ c.c.. 5/6: 1 c.c.. 6/6 2 c.c.	„	7/6
SODIUM SALICYLATE, *in varicose veins,* 3 c.c. 20%. 5/6; 30%. 6/6 .. 40%	„	7/6
SODIUM THIOSULPHATE, 0.45 and 0.6 gm., in 5 c.c. *Intrav. in Arsenical and Mercurial poisoning*	„	6/6
STOVAINE-GLUCOSE, aa., 5%. *for spinal anæsthesia,* 1 c.c.. 6/6 .. 2 c.c.	„	10/0
STROPHANTHIN (*hypod. and intrav.*), 1/100, 1/250, and 1/100 grain ...	„	4/6
THIOSINAMIN COMP. (*intram., hypod. or intrav.*). *in treatment of keloid, scar tissue, etc.* 1 c.c., 5/6 .. 2.5 c.c.	„	7/6
TUBERCULIN DILUTIONS (*subcut.*). *Dilutions are made under Licence of all the standard types of Tuberculin.*	each	2/6 to 4/6

In the absence of facilities "Sterules" of Distilled Water are useful for dilution. Boxes of 10 × 10 c.c. 3/6

"STERULES" to special formulæ, any size up to 100 c.c., are prepared promptly.

You may rely on immediate attention to postal enquiries.

What is ★MONSOL★ ?

MONSOL is a highly refined and efficient antiseptic prepared from Mond Oils.

MONSOL is a practical application of four essential principles, never before combined:—

(*a*) *Germicidal Power* (*b*) *Complete Penetration*
(*c*) *Harmless to Tissue* (*d*) *Healing Action*

Thus—**MONSOL** attacks all germs, whether surface or deep seated, without irritation or injury.

MONSOL products all combine these unique properties as no other preparations can do.

MONSOL BRAND

GERMICIDE AND DISINFECTANT

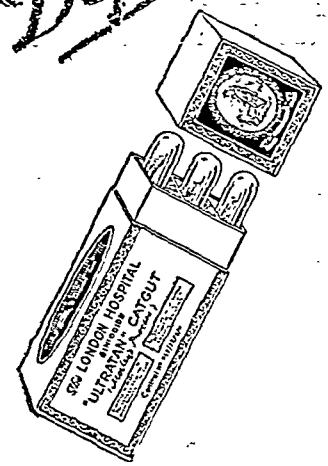
MONSOL	MONSOL OINTMENT	MONSOL CAPSULES
LIQUID for dressings, douches, packs, and all sick-room purposes	MONSOL THROAT PASTILLES	Keratin-coated for intestinal disinfection
	MONSOL DENTAL CREAM	

Manufacturers: The Mond Staffordshire Refining Co., Ltd., 47 Victoria Street London, S.W.1

Dependability

"ULTRATAN" LONDON HOSPITAL BINIODIDE CATGUT

(Morley's Process)



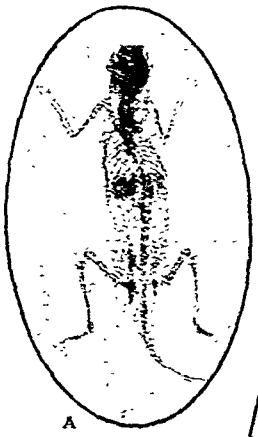
1 It is prepared at the London Hospital under strict antiseptic conditions
2 Sterilization of the gut starts before decomposition begins after the death of the animal
3 "Ultratan" Catgut is prepared for 10, 20, 30 and 40 days absorption
4 A feature of Biniodide Catgut is its great tensile strength
5 It is in continuous use, with unfailing success, in seventeen operating theatres in the London Hospital

Members of the profession are invited to visit the department at the London Hospital, Whitechapel, to inspect the process of manufacture throughout.

A Sample and Descriptive Booklet sent post free on application to

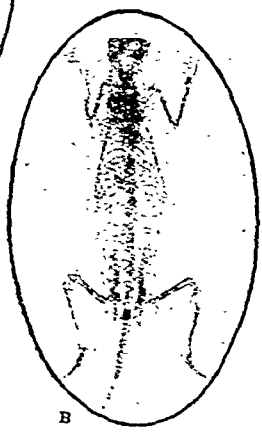
ALLEN & HANBURYS LTD.,
48 Wigmore Street, London, W. 1

The London Hospital Catgut may be obtained from all the leading Surgical Equipment Houses.



A

A—Skiagraph of rat rendered rachitic by deprivation of vitamin D.



B

B—Showing the curative effect of a daily ration of 0·005 grm. of Cod-Liver Oil.

The 'Allenburys'

'PERFECTED'

Cod-Liver Oil

Cod-Liver Oil is the richest available natural source of the fat soluble growth-promoting vitamin A and the antirachitic vitamin D. *There is no reliable substitute and satisfactory results can be ensured only by the use of the natural oil.* This season's oil has been tested independently in the laboratories of the Pharmaceutical Society of Great Britain and passed as fully active with regard to the vitamins A and D. *Each bottle bears a copy of the Society's Certificate.*

In amber bottles for protection against light at **1/6, 2/6, 4/6** and **8/6**

Descriptive literature and a clinical sample will be sent, post free, on application.

ALLEN & HANBURYS LTD., Bethnal Green, London, E.2

CANADA—66 Gerrard Street E., Toronto

UNITED STATES—90-92 Beekman Street, New York City

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

Reminders and Suggestions

For the Treatment of
INFLUENZA, PNEUMONIA, Etc.

CRYOGENINE (Lumière) — A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy.

Powder and Tablets: Dose—From 0.50 to 2.50 gm. daily as required.

ORARGOL — An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of *Rhinitis, Tonsillitis, and Naso-pharyngeal inflammations.*

Extremely valuable as a prophylactic against Colds and Influenza.

A Lecture
ON
ACUTE CEREBRAL LESIONS AT DIFFERENT AGES.

DELIVERED BEFORE THE WEST SUFFOLK DIVISION OF THE BRITISH MEDICAL ASSOCIATION, OCTOBER, 1928,

BY

S. A. KINNIER WILSON, M.D., F.R.C.P.,
PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR PARALYSED AND EPILEPTIC, QUEEN SQUARE.

ACUTE cerebral lesions may be reckoned among what my old teacher, the late Sir William Gowers, once called "the uncommonplaces of medical practice." Not occurring often enough to become familiar, if not banal, yet not so rare as to render ignorance of their nature and treatment pardonable, they are seen by the practitioner more frequently than by the consultant, and in nearly every instance necessitate his coming to quick decisions and adopting prompt therapeutic measures. Obviously he must have a certain confidence in his own diagnosis when such circumstances prevail, and must have at ready disposal some formulation of diagnostic elements on which to rely during the first hours after the lesion reveals itself. A waiting policy does not always serve at these times.

In this, as in many other instances, the problem is to know how to approach the problem. Working rules are necessary if he is to grasp the essential features of the situation and avoid being misled by non-essentials. Text-book descriptions doubtless cover all eventualities, but their application to the practice of medicine leaves him on occasion in perplexity. I do not pretend that the problem can be simplified by any rule of thumb devoid of exceptions and infallible in its working; all of us commit errors of diagnosis and of judgement, and sometimes hesitate not so much from ignorance as from fullness of knowledge. When this situation develops, another dictum of the same great clinical teacher deserves to be recalled: "Be decisive in your indecision"—in other words, be sure of your reasons for not being sure, and adopt measures calculated at least to do no harm.

One of the most convenient and practical ways of dealing with the problem of an acute cerebral lesion is by attending to the age of the patient. At any given age period, what are the probabilities? The generalizations sketched below have their value, relative though not absolute, and are worth bearing in mind.

I. IN CHILDREN AND YOUNG PEOPLE.

Numerically and proportionately less common in childhood and early adolescence, abrupt cerebral affections constitute no actual rarity and are often not a little disconcerting. Since the observer is able to dismiss all thought of degenerative lesions from his mind in such cases, the pathological possibilities are more or less restricted to toxic and toxi-infective processes, pressure, trauma, and blood-vascular states. Of these, the first-named form the majority.

1. Much the most frequent is one or other variety of *encephalitis*, by which pathological term is to be understood a brain infection, whether specifically known or not. A sporadic encephalitis (not, in all probability, identical with what is now called epidemic encephalitis)—sometimes described as acute non-suppurative encephalitis—is a fairly common affection of childhood, producing usually a hemiplegia and less often a diplegia. When a preliminary stage of malaise, fever, and vomiting, with headache, possibly with delirium and stupor, is succeeded by generalized convulsive attacks with unconsciousness, rigidity, cyanosis, and so forth, and followed by paralysis on one side of the body, the syndrome is not so sudden as to preclude a very good idea of its nature being formed. But in a minority of cases the paralysis supervenes abruptly on a convulsion, or even without the latter, just as it appears unheralded in a small proportion of cases of acute poliomyelitis. Diagnosis then is perhaps less definite, but the probability is not; lumbar puncture is likely to reveal a finding comparable (in greater or less degree) with that of acute poliomyelitis should the case be one of acute polioencephalitis—a poliomyelitis variant; if the fluid is negative, however, the case may none the less be one of encephalitis, though not occasioned by the virus of infantile paralysis.

In a recent instance a schoolboy was sent to bed with an ill-defined ailment—slight rise of temperature, headache, pains in the neck; on the third day he developed diplopia, followed by complete aphagia and a remarkable dysphonia, a high-pitched, "reedy," "piping" intonation which he was incapable of modulating. Lumbar puncture showed a fluid differing immaterially from the normal, and the case was fairly, as I think, classified in the group of acute bulbar encephalitis.

I have often thought that some of the obscure cases of quick death in seemingly healthy children, the sole symptoms being clouding of consciousness with respiratory or cardiac embarrassment and failure, are attributable to polioencephalitis of the medulla, of the class already mentioned—namely, that without recognizable prodromata. Here, indeed, lies one of the serious difficulties connected with polioencephalitis; no definite relation has been made out between the mildness or otherwise of the preliminary syndrome and of the paralytic consequences. The former may actually escape notice, or be ignored, yet palsy may set in after a truly fulminant fashion.

Of less diagnostic difficulty are the varieties of cerebral disorder arising abruptly in the course of one or other of the *specific fevers and exanthems*, and set down (in some instances at least) to encephalitis. These juvenile encephalopathies are well recognized, however rare their incidence and variable their actual pathology. They are known as an occasional development in scarlatina, diphtheria, measles, mumps, pertussis, typhoid, small-pox, etc., as well as in influenza, pneumonia, and other infections. The underlying pathological condition is more frequently a matter of surmise than of proof; sometimes a haemorrhagic encephalitis, in other instances it is a vascular state of haemorrhage, embolism, or thrombosis, or a cerebral oedema associated with nephritis, or a serous meningitis. In a valuable series of papers J. D. Rolleston[1] has collected information bearing on these rather out-of-the-way cases, as has recently also my former house-physician and present colleague W. P. H. Sheldon.[2]

Attention may next be directed to the occurrence of *encephalitis after vaccination* (ordinary cow-pox), a sequel that has aroused some concern in the course of the last three years, over one hundred cases having been recorded in that time (Lucksch,[3] Bastiaanse,[4] Turnbull and McIntosh,[5] Wiersma,[6] Perdrau,[7] Bouman,[8] and others). There can be little doubt that such cases were formerly extremely infrequent, and the conclusion seems justifiable that they are somehow connected with the times through which we are passing; at any rate, one theory at present offered is to the effect that encephalitis after vaccination is due to activation by the vaccine of another "invisible virus," conceivably that of epidemic encephalitis or a herpetic one. Valuable experimental evidence in favour of the view that the encephalitis is not due to the vaccine itself has been furnished by Pette.[9] Clinically, convulsions and hemiplegia seem to be rather common in vaccination encephalitis; an initial stage of general cerebral disturbance is usually definite and of some little duration, although localizing symptoms develop with rapidity. The pathological lesions resemble those of acute disseminated encephalomyelitis of the adult.

2. Of interest and importance is the group characterized by symptoms suggestive of *meningitis* or pointing to the existence of *meningeal reactions* of toxic or toxi-infective origin. Classified as meningismus or as circumscribed serous meningitis (both terms being as a fact rather indefinite from a pathological viewpoint), the type of case is that in which intracranial symptoms (cerebral, cerebellar, pontobulbar) develop unexpectedly and alarmingly early or late in the course of an indefinite illness, with mild meningeal indications, for which no source of infection is discoverable. Serous meningitis is the least sinister of all meningeal states; it consists chiefly in an increase of cerebro-spinal fluid in the appropriate cerebral and meningeal spaces, producing an internal and/or

external acute hydrocephalus, apparently always of a non-microbic character—in some instances (and these are the simplest diagnostically) a reaction to sepsis at some near but extra-meningeal spot (ear, nasal passages, tonsils). To this variety the term "meningitis serosa comitans" is sometimes applied. In numerous other examples of the affection, however, the meningeal reactions are localized (meningitis serosa circumscripta), producing focal symptoms and signs, although the underlying source seems to be a diffuse toxicosis of diverse kinds. Lumbar puncture yields an essentially negative fluid, sterile, with cytology little altered, but with perhaps a protein increase, and usually under considerable pressure. The remarkable feature of most cases is also a fortunate one; after withdrawal of fluid the symptoms are mitigated, and in not a few cases soon entirely disappear. I have been misled by cases of this kind on more than one occasion.

A little boy of 8 developed in the course of a few hours a complete right hemiplegia and aphasia, signs of general disturbance being minimal. No source of infection could be found. I diagnosed the case as one of encephalitis and gave a guarded prognosis. Lumbar puncture yielded a normal fluid under pressure, and within twenty-four hours thereafter the symptoms had completely vanished.

Cases of this kind are highly deceptive, but other examples of *meningitis serosa* simulate cerebral tumour (so-called pseudotumor cerebri) and are less calculated to give rise to acute cerebral symptoms.

3. We do well to bear in mind the possibility of insignificant *traumata* being succeeded after a variable interval by *sudden cerebral disturbance*. Trifling knocks raise haematomata on youthful heads with surprising ease. The serous meningeal reactions already alluded to may follow tearing of arachnoid tissues by trauma; in other cases subdural or subarachnoid haemorrhage results. I have seen more than one example of trivial injury turning out to be serious, but none so dramatic as that recorded long ago by Erichsen.

"A little girl was going downstairs with her mother to dinner. She said, 'I will go first, mamma,' and started to run downstairs, but she missed her footing and fell forwards, striking her head slightly against the wall. She felt a little dazed at the time, but went to her dinner, ate, and afterwards felt slightly sick. She was sent to bed, slept soundly, and was dead next morning. There was a clot found between the dura mater and the skull on the side of the head that had been struck, but no fracture."

The fatal injury may be so slight, indeed, that no concussion symptoms are produced, a point to which particular attention is directed. When we remember that in the growing child both periosteum and meninges are highly vascularized for purposes of nutrition, it is likely enough that corresponding to the visible "bump" where his head has been knocked is a haematoma greater or less in degree of the intracranial membranes. This state of affairs, in point of fact, has been found by Wood Jones,[10] who adduces evidence strongly suggesting a venous and not an arterial origin for the haemorrhage. Sheldon's[2] series embraces several cases belonging to this group; in one instance a child hit his head against a table; in another, a boy fell off a kitchen chair.

Consideration of this part of our subject naturally leads to the problem of what has been called *traumatic delayed apoplexy* ("traumatische Spätapoplexie"), a matter of peculiar medical and sometimes medico-legal importance. The condition is not confined to youthful cases, but may be conveniently referred to in the present section. A latent period of days or weeks may elapse between the date of the injury and the onset of ominous cerebral symptoms. Numerous instances of delayed apoplexy are now on record (Bollinger,[11] Marie and Crouzon,[12] Lambert,[13] Buzzard and Cunning,[14] Warrington,[15] Allen,[16] and others). For admission in the class the appended criteria require attention: (1) cases in which apoplexy might develop spontaneously must be rigorously excluded (syphilis, nephritis, alcohol, heart disease, arterio-sclerosis, etc.); (2) the injury must have been definite though not of necessity severe, or producing unconsciousness; (3) the symptoms of the lesion must have appeared within a short space of time and under observation. During the interval between injury and apoplexy cerebral symptoms of a general kind and slight in degree may be noted; sometimes they appear to be non-existent. In one of Sheldon's cases a child fell against a cupboard, and "several weeks" of seeming health elapsed ere vomiting and loss of consciousness set in, these symptoms preceding death by only a few hours. But in the Buzzard-Cunning case, after a trivial head injury through a fall, seventeen days of headache were succeeded by drowsiness and other symptoms of pressure, and a craniectomy revealed bleeding from the superior longitudinal sinus.

It is impracticable to lay down any exact time limits for cases coming within this category; only those can be admitted in which causal connexion between trauma and symptoms is reasonably definite and in which from the date of infliction of the former a reasonably brief period elapses ere the latter make their appearance. I have had to adjudicate in a case of right hemiplegia and aphasia developing suddenly four weeks after a trifling knock on the skull through the patient (a man of 46) striking an overhead rafter, and I decided against the diagnosis of delayed apoplexy.

4. Where some more or less obvious *blood state* is in existence the explanation of acute cerebral lesions in youthful subjects is not obscure. I need only allude in passing to the occurrence of haemorrhage, thrombosis, or embolism, or combinations of these, in heart disease; in marantic cases, in leukaemia, splenic anaemia of infancy, purpura haemorrhagica; in any severe anaemia, in scurvy, haemophilia, and so forth.

5. There remain for discussion the always difficult and disconcerting cases of sudden death from *haemorrhage* in children and adolescents, of which numerous examples have been published (cf. a useful paper by Hawthorne[17]). Unless an autopsy is obtained cases of this kind are shrouded in obscurity, and their pathology is a pure speculation; if the patient recovers it is equally so. Here we touch what Sir William Gowers once called "the old and inevitable antagonism between pathology and therapeutics." Each flourishes at the expense of the other, and the ends for which we gain our knowledge can be the chief obstacle to its acquisition.

Briefly, in my experience the *pathological possibilities* are: (*a*) bleeding from an unsuspected vascular intracranial tumour; (*b*) bleeding from an otherwise undiscoverable miliary aneurysm ("congenital aneurysm"); (*c*) bleeding from a structurally defective blood vessel without aneurysmal formation. A fourth possibility has been suggested by Goldflam[18]—namely, (*d*) bleeding of the nature of capillary oozing during hyperaemia following constriction—a disorder of vasomotor function. The term "spontaneous subarachnoid haemorrhage" is in vogue for cases of this kind, though it is somewhat misleading. Clearly, if evidence of aneurysmal formation or neoplasmic haemorrhage is discovered at necropsy the case should in point of fact be described under the heading of cerebral aneurysm or tumour, as the case may be. The literature on these types is considerable, clinico-pathological instances and useful reviews having been published by Symonds,[19] Beadles,[20] Fearnsides,[21] Turnbull,[22] Weber and Bode,[23] Marburg,[24] and many others.

As is to be expected, the symptomatology is highly variable, depending on both the degree and the site of the haemorrhagic extravasation. Elsewhere[25] I have given a full account of "spontaneous" leakage from a frontal tumour in a youth of 19; the extravasation spread through the ventricular system and passed under the basal meninges, reaching the vertex in one direction and the spinal cord in the other. In this instance the clinical picture for seventy-two hours was that of decerebrate rigidity. The usual syndromes of ventricular, cortical, pontine, basal haemorrhage may be encountered.

A recent example was the case of a healthy schoolgirl of 17, who, after two days of insignificant malaise diagnosed as nothing more than a cold, became unconscious at 3 o'clock in the morning and was dead at 9. Lumbar puncture yielded a fluid laden with fresh blood. No necropsy being granted the case remains as obscure as it is tragic.

I have also had occasion to observe more than one instance of cerebral haemorrhage in youthful subjects supervening apparently on excessive emotional disturbance. Such cases provide food for thought even if objective corroboration is awanting.

A married woman of 20 ascertained that her husband was conducting a liaison with another person. In a state of intense emotion she went to confront them with the righteous indignation of a young wife. After a painful scene she left the house and fell unconscious on the pavement outside. Two days elapsed ere consciousness returned, accompanied by right hemiplegia and complete motor aphasia. Now, when she is 45 years old, the hemiplegia remains, and a trace of the former speech defect.

Here, doubtless, we may imagine a miliary aneurysm or a weakened spot in the wall of the left Sylvian artery to have ruptured under the influence of the altered vascular balance attributable to excitement.

II. In Early and Middle Adult Life.

In the age periods comprised by the twenties, thirties, and forties most of the etiological factors already enumerated are still in the picture. Trauma, encephalitis, blood states, cardiac disease, and "spontaneous" vessel rupture must always be considered possibilities. To these we now add acute cerebral lesions associated with (1) pregnancy, parturition, and the puerperium; (2) neurosyphilis; (3) haemorrhagic pachymeningitis.

1. Much that is still enigmatic surrounds the occasional development of acute hemiplegia (or paraplegia) *before, during, or after confinement*. Half a century ago clinicians were attracted by the conception of "reflex paralysis"—sometimes also described as "urinary paralysis"; Sir Samuel Wilks[26] contended that a paraplegia might be induced by an external irritant, that "the blood vessels are thereby diminished in calibre, the blood supply to the spinal cord is diminished in amount and its power departs." He was concerned mainly with cases of temporary paralysis, and sought an explanation in irritation of vasomotor nerves innervating blood vessels. *Inter alia*, he made the theory of reflex paralysis apply to the case of paraplegia succeeding labour. About the same time Fussell[27] stated that cows not infrequently suffer from paraplegia after calving, that they lie down, unable to move their hind legs, and apparently have no feeling in them when they are touched. In about a fortnight recovery ensues. Similar phenomena are known to occur in pregnant mares.

Present-day conceptions have widened in range without gaining in precision. Puerperal hemiplegia (inclusive of *pre-puerperium cases*) includes a rather heterogeneous collection of morbid states. Apart from the ordinary causes (syphilis, cardiac disease, etc.), to which, of course, the pregnant woman as well as any other may be subject, certain processes are apt to develop in connexion with this physiological condition. A review by *Duhot*[25] informs us that of 46 cases 17 were occasioned by cerebral haemorrhage, youthful though the patient frequently was. Physiological hypertrophy of the left ventricle and increased richness of the blood are thought by themselves to be insufficient, and the additional factor of albuminuria is incriminated. Localized *cerebral oedema*, rather than haemorrhage, and the local effect of toxicosis ought not, however, to be overlooked. Another variety is meningeal haemorrhage, but its explanation is unfortunately not clear. It may develop in the absence of albuminuria or cardiac disease, or of any evident visceral or toxi-infective process. I may mention an ingenious theory to the effect that increased activity of the suprarenal glands in pregnancy, as disclosed by a condition of hypercholesterinaemia, leads to a rise of blood pressure from time to time, and so to meningeal haemorrhage.

But in other instances thrombosis instead of haemorrhage provides the causation, and its pathogenesis is equally indefinite, unless we fall back on the analogies alluded to above and assume not so much a "reflex" paralysis as one originating in *stagnation of viscous blood owing to* a weakly acting heart or a low blood pressure. The paraplegia of pregnancy (sometimes called Moxon's paraplegia) may result from a thrombosis of this kind in the long anterior spinal artery.

The physiological peculiarities of pregnancy and the puerperal state deserve more attention from the neurologist. Three cases of epilepsy occurring solely during pregnancy and in the absence of eclampsia have been reported by Curschmann.[29] Amelioration of the characteristic symptoms of *myasthenia gravis in the course of* pregnancy has long been known but never explained. The evolution of abnormal clinical conditions during a normal physiological process should surely check the misconceptions of those who persist in the habit of making "symptoms" constitute "diseases," and who with equal persistence *ignore the physiological nature of the former*.

2. Little need be said of *neurosyphilis* in these days, when any suspected case of acute cerebral disorder can be made to run the gauntlet of serological tests and a verdict obtained within a few hours. Clinically, neurosyphilis turns up in unexpected quarters and in unwonted guise. A sudden loss of consciousness with epileptic fits and consequent paresis may be the first indication of incipient general paralysis; an acute hemiplegia or monoplegia may betray an *endarteritis syphilitica*, or a little-suspected *gummatous meningitis*; *syphilitic* cerebral haemorrhage, less well recognized and less often envisaged, should not be overlooked.

Only a week or two ago sudden headache, sickness, malaise, and rise of temperature, followed by right facial weakness and considerable aphasia, led me to diagnose encephalitis in the case of a man of 35; but routine insistence on the tests of the clinical laboratory enabled me next day to correct it to neurosyphilis, with corresponding improvement in the prospects of recovery.

3. A rarer affection is that known as *pachymeningitis haemorrhagica interna*, the pathology of which is explanatory of its somewhat unusual symptoms. Occurring more frequently among those addicted to alcohol than others, it is signalized by intense headache, vomiting, sometimes convulsions, and abrupt loss of consciousness. There is not uncommonly a rise of temperature accompanied by signs of meningeal irritation; a bloody spinal fluid is obtained by puncture, with marked increase of albumin and globulin; smears are always negative and cultures sterile. Recovery ensues, hastened by withdrawal of spinal fluid, but recurrence of the attacks constitutes the danger. In the cases I have observed myself neurosyphilis was excluded, yet the basis of some recorded instances appears to have been of this nature (Hassin[28]).

Thus on his return home from a city dinner a middle-aged man suddenly fell unconscious on his bedroom carpet, with generalized convulsions and immediate rise of temperature. Meningeal symptoms appeared and a clinical diagnosis of some form of meningitis was made. Only on the fifth day was lumbar puncture resorted to, when a clear fluid of an extraordinary pink-orange-yellow colour was withdrawn. Spectroscopy showed it to be full of haemoglobin derivatives. In view of the history and of the habits of the patient a diagnosis of pachymeningitis haemorrhagica interna was made, and confirmed by the subsequent course of the case.

This example of the condition is almost identical with one reported by *Fried*.[31] Another instance, however, occurred in a younger man, in whom three separate attacks similar to the above developed at approximate intervals of six months; recovery was much slower after the second, and a fourth was fatal. At necropsy the peculiar stratiform alternation of membranous and haemorrhagic layers over the postero-superior and postero-lateral aspects of the encephalon was at once recognized.

III. In Later Life.

If we assume with some arbitrariness that the *fiftieth* year of life ushers in a degenerative period, we may expect thereafter acute cerebral affections, of which the commonest symptoms are hemiplegia, aphasia, and hemianopia, and the commonest lesions vascular. Naturally the clinician must not forget the exceptions to the general rule; Bright's disease may bring cerebral disaster in its train long before 50, and families are known that are unhappily distinguished by hereditary apoplexy.

Vascular lesions, then, haemorrhagic or thrombotic, constitute by far the major portion of the cerebral attacks of later years: these should always be regarded as cerebral *traumata*, and treated by rules applicable to lesions of the *vascular* system. Differential criteria between haemorrhage and thrombosis often appear more impressive on paper than during anxious moments at a bedside; diagnosis is reached in numerous instances fully as much by scrutiny of the exact order of events as by consideration of the objective signs. In the subjoined paragraphs an outline is given of the points to weigh before committing oneself to a precise opinion. The condition of the vascular system is at least as significant in this connexion as the nature of the cerebral syndrome.

1. Inquiries directed towards the question of previous attacks may throw a sidelight on the present one. If slight seizures have occurred previously thrombosis is suggested; if a single severe previous attack, either. There may have been thrombosis originally, and haemorrhage now, or vice versa.

2. Asking next for the details of the present illness, the clinician notes that a more or less definite aura and a certain measurable duration for the unfolding of the attack characterize thrombosis, whereas there is little or none of this in the other process. Physical or mental exhaustion precedes thrombosis, it may be, but has little if any bearing on the occurrence of haemorrhage, as has, for that matter, the question of previous excitement. Ernest Jones[32] has shown that quite a proportion of haemorrhage cases (subsequently confirmed) have their onset during rest or sleep. These are points of some moment, for if the ictus is attributable to a combination of special circumstances rather than to severity in degree of vascular change the prognosis as regards recurrence is proportionately better.

3. At the bedside, commencing with the state of the pulse and heart, the examiner concludes that a feeble pulse and weakly acting heart suggest thrombosis; a full and perhaps bounding pulse, with cardiac hypertrophy and a blood pressure above normal for the patient's years, is in favour of haemorrhage. Thickened or tortuous peripheral vessels indicate either, as does the presence of albuminuria demonstrable in catheter specimen or otherwise. Similarly, retinal haemorrhages noted with the ophthalmoscope do not favour one diagnosis rather than the other, unless they happen to be severe and massed, in which case they point to cerebral bleeding.

4. Attention is also given to the loss of consciousness. Only if a large vascular area is out of action is unconsciousness likely to accompany thrombosis, whereas the laceration caused by extravasated blood inhibits the cortex, according to some, by irritation of corticipetal systems. Enduring unconsciousness strongly favours haemorrhage; a short initial loss, thrombosis. In basal, pontine, and ventricular cases the mechanism of production of the symptom consists in general (cerebral) vaso-constriction by excitation of a vasomotor control centre in the medulla. Should the obscuration of consciousness, trifling at first, steadily deepen as the hours pass, an ingravescent extravasation is indicated; yet in progressive thrombosis a not dissimilar phenomenon is occasionally remarked. The duration of these is never so prolonged, nor is there the same dubiousness of continuity, as may sometimes be observed in the cases of delayed traumatic apoplexy alluded to above.

5. As for concomitant epileptic seizures, if Jacksonian their repetition manifests a thrombotic process; if generalized, either that or haemorrhage. Since cortical vessels are more prone to the former than the latter the differential value of the symptom is explained.

6. Rise of temperature does not of itself furnish a means of distinguishing. It points to implication of the upper pons and is seen typically in pontine, basilar, and ventricular cases. Its steady and fairly rapid heightening is suggestive of early death.

7. If now the observer turns to other possible localizing indications apart from Jacksonian attacks, during the period of unconsciousness he may readily enough be able to diagnose capsular, pontine, unilateral, or bilateral sites of invasion, but of themselves these do not serve in differentiating between the two chief processes under discussion. The case is rather altered when consciousness returns. He may then be in a position to note that an enduring aphasia favours occlusion, since, as already mentioned, cortical thrombosis is as a fact more frequent than cortical extravasation. Again, hemianopia suggests a similar vascular origin, haemorrhage in the distribution of the posterior cerebral being distinctly rare.

With various interesting phenomena that can be demonstrated during the period of physiological decortication or decerebration (for example, the reflexes of Magnus and de Kleijn) I am not here concerned, as they do not shed light on the nature of the vascular process underlying the neural semeiology.

Since *embolism* may occur at any age, roughly speaking, I have left its consideration to the end. It does not present those difficulties which seem to be inseparable from the other two, except perhaps when the circumstances are unusual. Thus if the practitioner finds a patient with mitral stenosis and a weakly acting heart at the degenerative period, is his acute cerebral lesion embolic or thrombotic? Again, war experiences have shown how traumatic thrombosis of the internal carotid may cause a sudden cerebral attack by detachment therefrom of an embolus (Colledge and Dunn[33]).

When examination reveals a lesion of the vascular system in the emboligenic circulatory area, as it may be called, diagnosis of an acute cerebral ictus without premonitory symptoms can rarely if ever be erroneous. Infective endocarditis can scarcely be overlooked, although a presystolic murmur may be missed and milder endocarditic manifestations disappear.

Concluding reference to the controversial question of *temporary or transient hemiplegias* and other analogous cerebral disorders must of necessity be brief. The reality of these clinical disturbances is, of course, undeniable, but their pathogenesis is in the nature of things likely in most instances to be matter of speculation rather than of proof. Too facilely has acceptance been voted to the theory assigning them to an angiospasm—a transient constriction of a cerebral vessel thought to be itself in a degenerating condition; several weighty considerations militate against this view. (1) Leonard Hill[34] has shown experimentally that the cerebral circulation passively follows changes in general arterial and venous pressure, and is controlled by bulbar centres acting on the general circulatory system. If cerebral arteries are constricted corresponding capillaries become congested with venous blood—not emptied, with resultant local anaemia. (2) The pial network of vessels is so closely interwoven that symptoms from strong and persistent localized cramp in some of its twigs seem improbable, as collateral supply would supplement the arrest (Allbutt). (3) All arteries under the control of vasomotor nerves react to adrenaline by contraction, but the cerebral vessels do not (Florey[35]). (4) The tacit assumption is made that arterio-sclerotic arteries are specially prone to spasm, yet in that state the muscular elements have lost their contractility by undergoing fibrous degeneration. (5) Advocates of the theory of angiospasm do not appear to have faced the difficulty that the local cerebral anaemia of the motor zone which they postulate is unaccompanied by Jacksonian or general epilepsy; yet evidence has collected to demonstrate the association of hyperexcitability with cerebral vascular constriction, even if temporary.

The truth is insufficient attention has been given to the occurrence of microscopic organic lesions as a foundation for the symptom-complex, transient and recurrent, set down to angiospasm (Achard, Foix, and Leblanc,[36] Evans,[37] and others). Again, if a vessel is degenerated transient reduction of general blood pressure may result in a failure to maintain the column of blood against peripheral resistance, or to overcome partial obstruction; hence the development of transient paresis or paralysis from relative ischaemia. I do not doubt, further, that this is the correct explanation of those cases in which transient amaurosis is stated to coincide with observed spasm of retinal vessels (Lundie,[38] Bruner[39]); because of passing hypotension the artery may seem to diminish in calibre and perhaps actually do so, yet of arteriospasm in the strict sense there need be no trace. In fine, other possibilities than angiospasm may legitimately be utilized in the elucidation of transient cerebral attacks; and since this is so the physician need not seek a pathogenesis capable of being applied universally, and should realize the intrinsic variations among them on the clinical side as well.

THE TREATMENT OF COLLES'S FRACTURE.

BY

A. S. BLUNDELL BANKART, M.Ch.Cantab., F.R.C.S.,

ORTHOPAEDIC SURGEON, MIDDLESEX HOSPITAL, ETC.

THE admirable short paper by E. D. Grasby and S. R. Trick in the *British Medical Journal* of March 2nd (p. 391), following upon that of Edwards and Clayton in the *Journal* of January 12th, prompts me to offer a few remarks on the treatment of Colles's fracture.

Colles's fracture is at once the commonest (sharing this distinction with fracture of the clavicle), one of the easiest to treat, and generally the worst treated, of all fractures of the human body.

The first-mentioned paper is "an endeavour to ascertain the causes for the imperfect results that obtain from the usual methods of treatment at present adopted." The principal conclusions arrived at are:

> "1. Colles's fractures without displacement yield uniformly good results, as observed two years after the injury.
> "2. Where displacement was a marked feature of the fracture the results two years after the injury are invariably unsatisfactory.
> "3. The disability was in each case due to osteo-arthritis in the inferior radio-ulnar joint, resulting from incomplete reduction."

From this we must infer that at a great London teaching hospital a Colles's fracture is never properly reduced. For, apparently, when the displacement is not considerable, reduction is not considered necessary, and, when displacement is considerable, the result is invariably unsatisfactory owing to incomplete reduction. We need not, however, infer that the results so candidly reported from this clinic are in any way exceptional. They are indeed the usual results of the methods of treatment at present adopted. I personally never, or hardly ever, see a case of Colles's fracture which has been properly reduced, although many of the cases that I see have had some sort of manipulation previously. The reason for these uniformly bad results is that the method of reduction almost universally employed—namely, that advocated by Sir Robert Jones—is entirely inadequate in the hands of the majority of those who have to treat these cases.

In the classical Colles's fracture—and most cases are of this type—there are three characteristic displacements of the lower fragment of the radius in relation to the upper—namely, (1) displacement upwards and backwards; (2) abduction to the radial side; and (3) rotation about a transverse axis—that is, backward tilting of the lower articular surface, the importance of which is rightly emphasized by Edwards and Clayton. Each of these displacements must be deliberately corrected if a good result is to be obtained.

Colles's fracture is produced by great force—that is, the whole weight of the falling body upon the fixed wrist—and *it requires great force to reduce it.* The reduction of a Colles's fracture is a matter of sheer force; there is no trickery about it whatever.

General surgeons as a rule have no conception of the amount of force that orthopaedic surgeons can, and often do, employ in quite ordinary manipulations, and I think that some orthopaedic surgeons hardly realize it themselves. It may be that the powerful hands of Sir Robert Jones (and some others) can reduce a Colles's fracture in any manner that he chooses; but I am convinced that the method which he advocates is quite inadequate in the hands of the great majority of those who have to deal with Colles's fractures.

For general use there is no method to compare with that of *reduction over a wedge.* By this method the upper fragment is fixed, and the lower fragment is compelled by sheer force to go in whatever directions the operator wishes. Briefly the actual procedure is as follows:

The patient must be fully anaesthetized. Some expert anaesthetists can give gas or gas and oxygen for long periods, and can even obtain muscular relaxation (with luck), but this is quite exceptional. As ordinarily given, "a whiff of gas" is entirely inadequate for the proper reduction of a Colles's fracture. In these circumstances the reduction is always hurried, the patient is usually stiff or moving, and, above all, there is no time for a critical review of the reduction before he comes round, nor for a repetition of the manipulation if it should be found to be incomplete. The reduction should be done deliberately with the patient fully anaesthetized. I think that regional (brachial plexus) anaesthesia might be employed here much more often than it is.

For the manipulation the fracture is laid flexor surface downwards across the wedge,* so that the lower end of the upper fragment rests directly on the wedge. For the right side it is convenient to have the wedge lying on the table by the patient's side; for the left side (unless the surgeon is left-handed) it is more convenient to have it on an outlying small table. The upper fragment is firmly held by the surgeon's left hand on the wedge. The lower fragment is gripped by the surgeon's right hand with the thumb on top and the ball of the thumb directly over the prominence which the displaced lower fragment makes on the dorsum. The lower fragment is now forced downwards and forwards and towards the ulnar side. The amount of force required varies in different cases, but in all cases it is considerable, and I have many times put the whole weight of my body on to this fracture in order to reduce it properly. At the end of this manœuvre the backward tilt of the lower fragment is corrected by a sharp forward flexion movement.

Many surgeons make a point of first disimpacting the fracture by dorsiflexing the wrist and temporarily increasing the deformity. This is harmless, but unnecessary. The only objection to it is that it is apt to make a surgeon think that he can reduce the fracture by some clever manœuvre instead of by force. In reducing over a wedge disimpaction occurs just as readily as soon as the lower fragment is made to move, and then all that is necessary is to force the fragment into its proper position.

After the reduction the fracture should be critically examined. The positions of the styloid processes should be noted and compared with the normal. The prominence on the dorsum should be felt for, to make sure that it has quite disappeared, and it should be seen that the forward concavity of the lower end of the radius is restored. Lastly, the position of the hand as it hangs freely in relation to the lower end of the radius should be noted. If any part of the deformity remains uncorrected, the manipulation should be repeated.

There is very little tendency for the deformity to recur after a Colles's fracture has been properly reduced, unless the wrist is dorsiflexed, or the splint which is applied presses the lower end of the radius backwards.

The popular Carr's splint, as originally designed and as supplied to general practitioners and commonly used by them, is a bad splint, because it presents a flat surface to the normal forward concavity of the lower end of the radius and so causes the lower fragment to be tilted backwards. As padded up and applied by experts it is, no doubt, quite efficient, but then it is no longer a "Carr's splint."

* The so-called orthopaedic wedge is merely a short round horizontal bar covered with rubber, standing about four inches high on a firm base. For those who want one occasionally and have not got one, I may add that an ordinary flat iron, borrowed from the kitchen, with its round horizontal handle covered with a folded towel or other soft material, makes a perfectly good "orthopaedic wedge."

Colles's fracture should be put up with the wrist moderately flexed. The best position is that in which the hand hangs naturally when it is unsupported and the muscles are relaxed under the anaesthetic. No splint is more efficient or more comfortable than a plaster strip moulded to the flexor surface of the forearm and hand, leaving the fingers free.

The proper use of plaster-of-Paris requires a little practice, but I would submit that the putting up of a Colles's fracture in plaster is within the capacity of any practitioner; it requires less special knowledge and skill than the alteration of an unsuitable splint in order to make it suitable.

An assistant supports the elbow and steadies the limb by making light traction downwards and forwards on the middle fingers. The part is wrapped in a layer of cotton-wool over which an ordinary bandage is applied firmly, but not tightly. A four-inch plaster bandage is placed in warm water, and, when bubbles have ceased to rise, it is lightly squeezed and then applied evenly round and round the limb from the elbow to the middle of the hand. Three or four bandages are applied in like manner, and as soon as the plaster is set it is cut up each side with a sharp scalpel, and the top or dorsal half is removed. The lower half remains as the splint, and it is kept on with an ordinary bandage.

It has been suggested that this fracture should be put up with the forearm supinated, as is usually done with other fractures of the radius and ulna. But the supinated position is much more irksome to the patient, and I doubt whether it is really necessary in this case. Colles's fracture is produced by a fall on the pronated hand and it is impacted in the pronated position. In reducing it by the method described the lower fragment is forced back into its original—that is, normal—position in relation to the upper fragment, and if it is allowed to heal in this position normal movements should follow.

Massage and movements of the fingers are usually begun a day or two after the reduction, and movements of the wrist-joint in about ten days to a fortnight. But these times are of little importance as compared with the complete reduction of the deformity.

In conclusion, is it too much to hope that surgeons in charge of fracture departments allow their house-surgeons and dressers not merely to watch, but actually to do these manipulations with their own hands? Outside the immediate vicinity of large hospitals the great majority of Colles's fractures will be and must be treated by general practitioners, and the actual reduction of a few of these fractures under supervision is worth more to the future practitioner than all the demonstration that can be given.

VALUE OF THE HINTON TEST IN THE SERUM DIAGNOSIS OF SYPHILIS

IN COMPARISON WITH THE KAHN AND WASSERMANN REACTIONS.

BY

JOHN H. FERGUSON, B.A.OXON., M.D.HARVARD,

AND

EMILY C. GREENFIELD, M.B., CH.B.CAPE TOWN,

(From the Department of Bacteriology of the New Medical School, University of Cape Town.)

HAVING seen with interest the results of the new Hinton test as applied in the Wassermann Laboratory of the Harvard Medical School and in the pathological laboratory of the Massachusetts General Hospital, Boston, U.S.A., and been fired with Dr. Hinton's enthusiasm during a personal demonstration and discussion of his test, we decided to examine it in a comparative manner with our routine "Wassermann" specimens from the Somerset Hospital, the Peninsula Maternity Hospital, and, in a special series of cases through the kindness and courtesy of Dr. C. Kevin O'Malley, from the venereal disease clinics of the Health Department of Cape Town. One of us (J. H. F.) is responsible for the Hinton tests, the other (E. C. G.) for the Kahn and Wassermann reactions.

THE HINTON TEST.

Our basis for the test is the technique used by Dr. Hinton in June, 1928, which embodies some important modifications (then unpublished) of his original test as appearing in the *Boston Medical and Surgical Journal* of June 16th, 1927 (pp. 993–996).[1] We have used the test with this technique throughout, and have also subjected the procedures to critical experimentation and study, as will appear in the sequel.

The details of the Hinton test, as we have it in a personally annotated reprint with Dr. Hinton's own unpublished modifications (to June, 1928), are briefly set forth as follows:

The test is an "agglutination," by syphilitic serums, of a suspension of cholesterol in *glycerinated* hypertonic saline containing a mere trace of the alcohol-soluble, ether-insoluble extractives of beef muscle. The addition of the glycerol is the main feature of difference from the Kahn, the Sachs-Georgi, Sigma, Meinecke, and other "flocculation" methods of diagnosing syphilitic serums.

Preparation of Reagents.

The "antigen" or "indicator" is prepared from beef muscle (preferred by Hinton to beef heart). The method follows that described by Neymann and Gager,[6] and by Kahn.[2] A small quantity, say 1/2 lb., is freed from fat and connective tissue, chopped and minced, and dried for four or five days on a tray in an oven with a thermostat set at 55° C. It is then powdered, and extracted by vigorous hand-shaking in a stoppered graduate, using ether in the proportion of 1 gram of powder to 4 c.cm. of ether. The process is repeated four or five times until the ether comes away clear, and the residue collected on filter paper and dried. It is then extracted in a glass-stoppered bottle with 95 per cent. alcohol in the proportion of 1 gram of dried residue to 5 c.cm. of alcohol. Extraction is continued for three days at room temperature, and the "indicator" ("antigen") is then filtered off. To every 1 c.cm. of extract is now added 9 c.cm. of a 0.7 per cent. solution of cholesterol in absolute alcohol (prepared several days previously).

The "stock indicator," as Hinton calls it, keeps indefinitely in stoppered bottles of 50 to 100 c.cm. capacity in a dark cupboard at room temperature. The "indicator" actually used for the test is a glycerinated suspension of the cholesterolized antigen *freshly* made up with sodium chloride solution on the day it is to be used. Hinton now makes up a 3 per cent. as well as a 5 per cent. sodium chloride suspension. Two parts of the 5 per cent. (or 3 per cent.) NaCl are added to one part of "stock indicator" pipetted with a clean dry 5 or 10 c.cm. pipette into a 100 c.cm. stoppered graduate. This is shaken vigorously and left for half an hour. Twelve parts of saline are added, the suspension is shaken, and finally, after adding fifteen parts of 50 per cent. glycerol, again shaken thoroughly.

Hinton finds it unnecessary to "inactivate" the serum to be tested, but where routine Wassermann tests are being done it will have been "decomplementized" by heating to 55° C. for half an hour.

The test is carried out in three 10 mm. and 100 mm. (serum) tubes conveniently held in a numbered (Wassermann) rack. This should be of brass and have three shelves to stand immersion without upsetting the serum tubes.

To Tube 1 is added 0.1 c.cm. of serum and 0.5 c.cm. of 5 per cent. NaCl suspension.
To Tube 2 is added 0.3 c.cm. of serum and 0.5 c.cm. of 3 per cent. NaCl suspension.
To Tube 3 is added 0.5 c.cm. of serum and 0.5 c.cm. of 3 per cent. NaCl suspension.

The tubes are shaken thoroughly and placed in a shallow water-bath at 37° C. for six to sixteen hours. The test needs about 1 c.cm. of serum, and the quantities are easy to pipette.

A positive reading consists in a definite "agglutination" of the cholesterol suspension into more or less coarse clumps, with a complete clearing of the medium. A good positive reading in at least one tube (generally the first) constitutes a positive diagnosis of syphilis.

Modifications of Technique.

As a result of our experimentation with the test we submit the following conclusions and modifications of the technique:

1. The saline emulsion of our antigen* when made up with 5 per cent. NaCl is slightly too unstable, tending to "auto-agglutinate," whereas the 3 per cent. NaCl suspension is definitely too stable and too "inert," giving few positives. We found that a 4 per cent. NaCl-glycerol suspension gave uniformly better results without the needlessly extensive range of sensitiveness intended with the more complicated two-dilutions technique.

* Antigen preparations would appear to vary slightly in sensitivity, as we have noticed in using different batches of antigen.

2. The suspension becomes most sensitive if allowed to stand for half to three-quarters of an hour before use.
3. The 4 per cent. NaCl suspension is added in 0.5 c.cm. amounts to each of the three tubes containing respectively 0.1, 0.3, and 0.5 c.cm. (or 0.1, 0.2, and 0.4 c.cm.) of "inactivated" serum. We use a 20 c.cm. burette graduated in one-twentieths of a cubic centimetre, and find that this makes the addition of 0.5 c.cm. of the suspension to a large series of tubes a rapid and accurate process.
4. *To ensure thorough mixing, each tube is shaken with the* mouth held loosely between the thumb and forefinger (one tube in each hand); and a rackful of tubes may be shaken by hand in this way with remarkably little trouble and loss of time.
5. Keeping the tubes overnight in the water-bath or incubator at 37° gives the clearest readings. (This would seem to be indispensable, as with a room temperature of 22° to 26° unreliable results were obtained, and preliminary incubation at 55° C. for half an hour to an hour did not improve these results.)

Modified in this way the readings are for the most part clear-cut. Zone phenomena are infrequent and obvious.

Pseudo-Reactions.

A pseudo-reaction is sometimes obtained. For the most part this consists of a fine even flocculation, evident in all three tubes, and tending to be most marked in the tube with the largest amount of serum. On a few occasions this was quite confusing with our use of Hinton's "two-strength" technique, but the fact that there was not much pseudo-agglutination in the 0.1 c.cm. tube caused us to suspect the result in every case. With the 4 per cent. suspension these pseudo-reactions are much less marked and have never given the slightest trouble in reading in 114 cases (vide infra). Hinton emphasizes the clarity of the fluid in which the flocculi float in the case of the true as contrasted with the pseudo-reaction. It may be said that these pseudo-reactions are of slight practical importance and give little or no trouble after a short experience with the tests. Pseudo-reactions, it must be remembered, complicate the Kahn and other techniques, and even the Wassermann reaction is not wholly free from difficulties in reading. As to the validity of the test, Dr. Hinton is, to our certain knowledge, bringing out data from a very large number of observations, and our results support his personally expressed contentions fairly well.

THE KAHN REACTION.

R. L. Kahn, in 1921, appreciating that the "precipitate" in the heterophilic flocculation tests for syphilitic serums was lipoidal in character, as contrasted with the serum globulins in specific immune precipitations, was led to study the variable factors in the reaction, and to evolve a method of stabilizing the conditions of flocculation (precipitation). This method involves:

1. Choice of highly unstable antigen-saline suspension.
2. Optimum concentration of ingredients.
3. Quantitative relation between antigen suspension and serum.
4. Agitation to bring forth the precipitate, especially in weak serums.

The antigen is an alcoholic extract of dried beef heart from which the ether-soluble "non-reactive" extractives have been removed by a careful method of extraction based upon that of Neymann and Gager[6]: 0.6 per cent. of cholesterol is added as experiments indicate that this is the optimum. The optimal amount of saline to add to the cholesterinized antigen is determined by a preliminary antigen titration in which varying quantities of 0.85 per cent. NaCl are added in a standard manner, and note taken of the solubility of the precipitate on the further addition of "test" quantities of saline. The antigen saline proportion we found to be the optimal averaged 1:1, and this is made up ten minutes before the test. We took this titre to indicate correct sensitivity as we had no standard antigen for control-standardizing purposes.

The test proper is conducted with heated serum (56° C. for half an hour being the standard). To 0.05, 0.025, and 0.0125 c.cm. of antigen dilution in agglutination tubes in a suitable (Sigma) rack are added 0.15 c.cm. amounts of heated undiluted serum. We used thorough shaking, by hand, for three minutes to facilitate the reaction. No addition of saline (as recommended by Kahn) was found necessary to make readings clearer. We noted, however, that clear-cut reactions were not immediate, and indeed several hours were necessary before the routine readings could be taken. This led to our leaving the racks at room temperature overnight and reading them along with the Hinton reactions next morning. We consider that this delayed reaction might indicate some lack of sensitivity in our antigen suspension, but conclude that all other details agreeing with the standard Kahn routine technique, our late (eighteen-hour) readings may be taken as reliable.

Pseudo-reactions were noted in a few cases and were apt to be confusing; our eighteen-hour readings, however, were, on the whole, clear-cut and easy to read. The question of the validity of the results, and the possibility of "false positives," may be referred to a consideration of our tables, and to the experience of other workers.[7] We used cerebro-spinal fluids without the preliminary *preparation* advocated by Kahn, so as to compare with the Hinton and Wassermann tests. We conclude from our limited observations that this led to very inferior results.

THE WASSERMANN REACTION.

We have employed as a routine the No. 4 method of the Medical Research Committee's Special Report Series No. 14 (1918),[4] which is a standardized method calculated to yield results, both positive and negative, of the highest degree of validity and reliability.[5] Our complement *minimum haemolytic dose averaged 1 in 30: and the minimum haemolytic dose of the haemolytic immune body 1 in 1,500.*

The serums delivered to us were not always satisfactory, and a number had to be refused on account of haemolysis, gross turbidity, etc. Certain serums with a definite degree of haemolysis were put up and often gave definite reactions. Such of these as were controlled by a subsequent test we have thought fit to include in our series. Anticomplementary serums were ignored, but it is to be noted that in a number of these the Hinton and Kahn tests gave good positives. Wassermann readings were taken immediately after removal of the racks from the water-bath, as it was found that standing even for a short time at room temperature furthered haemolysis and was apt to change weakly positive tubes to negatives (complete haemolysis). Our series of 612 cases includes some 30 odd repeat observations.

TABLE I.—In a comparison of the Hinton and Wassermann tests 612 examinations gave:

Complete agreement in 551 cases (90 per cent.)—	
Both tests negative	384
Both tests positive	167
Doubtful agreement in 15 cases (2.5 per cent.)—	
Hinton negative, Wassermann weak...	4
Hinton positive, Wassermann weak..	8
Hinton weak, Wassermann negative	3
Disagreement in 46 cases (7.5 per cent.)—	
Hinton positive, Wassermann negative	34
Hinton negative, Wassermann positive	12

TABLE II.—In 460 of these cases, in which the Kahn test was also performed, the Hinton compares with the Wassermann as follows:

Complete agreement in 420 cases (91.3 per cent.)—	
Hinton and Wassermann negative	238
Hinton and Wassermann positive	122
Doubtful agreement in 4 cases (0.9 per cent.)—	
Hinton negative, Wassermann weak..	4
Disagreement in 36 cases (7.8 per cent.)—	
Hinton positive, Wassermann negative	31
Hinton negative, Wassermann positive	5

TABLE III.—In a comparison of the Kahn and Wassermann tests in this series of 460 cases we get:

Complete agreement in 428 cases (93 per cent.)—	
Both tests negative	310
Both tests positive	118
Doubtful agreement in 8 cases (1.7 per cent.)—	
Kahn weak, Wassermann negative	4
Kahn negative, Wassermann weak	3
Kahn positive, Wassermann weak	1
Disagreement in 24 cases (5.5 per cent.)—	
Kahn positive, Wassermann negative	15
Kahn negative, Wassermann positive	9

TABLE IV.—Comparing the Hinton and Kahn tests we have:

Complete agreement in 425 cases (92.4 per cent.)—	
Both tests negative	297
Both tests positive	128
Doubtful agreement in 4 cases (0.9 per cent.)—	
Hinton negative, Kahn weak...	4
Disagreement in 31 cases (6.7 per cent.)—	
Hinton negative, Kahn positive	6
Hinton positive, Kahn negative	25

TABLE V.—Comparing the three tests for these 460 cases, we have:

Complete agreement in 407 cases (88.5 per cent.)—	
All three tests negative	290
All three tests positive	117
Doubtful agreement in 8 cases (1.7 per cent.)—	
Hinton and Wassermann negative, Kahn weak ...	4
Hinton and Kahn negative, Wassermann weak ...	3
Hinton negative, Kahn and Wassermann weak ...	1
Disagreement in 45 cases (9.8 per cent.)—	
Hinton and Kahn negative, Wassermann positive	4
Hinton negative, Kahn moderately positive, Wassermann positive	1
Hinton and Wassermann negative, Kahn positive	4
Hinton and Kahn positive, Wassermann negative...	11
Hinton positive, Wassermann and Kahn negative...	20
Hinton and Wassermann positive, Kahn negative	5

DISCUSSION.

Comparing these tables, we note that the Hinton and Kahn tests agree fairly closely with the Wassermann reaction, the Kahn slightly more closely than the Hinton. To evaluate the small differences would necessitate clinical data to supplement the serological findings. Satisfactory clinical data were not obtainable in our present series, and we are now at work on a smaller series of selected cases with a view to obtaining a correlation of serological findings with reliable clinical evidence. These results, together with further investigations relating to the fundamental principles underlying the Hinton test, we hope to publish in due course.

We may note in our present series, however, that the Hinton test gives more "positives" than either the Kahn or the Wassermann, and this means either that the test is more sensitive or that it gives a greater number of "false positives." The Kahn also gives a slightly greater number of positives than the Wassermann, and a number of authorities feel that the question of "false positives" with the Kahn calls for some hesitancy in accepting the result in the individual case.[8] It is agreed that false positive Wassermann reactions are very rare under the standardized conditions of the No. 4 method. A ±, and even a + Wassermann, however, demands a repeat, and perhaps a provocative injection of salvarsan, if the clinical evidence of syphilis is insufficient. We have one or two + and − Wassermann reactions, with a negative Hinton, that would need this corroboration of the Wassermann result.

The Hinton test, in our opinion, gives more "false positives" than the Wassermann, but probably (as far as our evidence goes) fewer than the Kahn. This is advanced tentatively, especially in view of the criticisms of our Kahn technique which we have offered above. On the other hand, we feel strongly, on the evidence of a number of the cases having highly suspicious histories, and sometimes giving a positive Kahn reaction also, and occasionally a positive Wassermann on repetition, that the majority of positive Hinton reactions (where the Wassermann is negative) do denote a greater sensitivity of the flocculation test. In the noticeably small number of cases —namely, 5 in our smaller series, and 12 in the larger series—where the Wassermann reaction is positive and the Hinton negative, such evidence as we can command suggests that the inconclusive nature of the ± or + single Wassermann must be considered, as well as the alternative explanation that the Hinton "misses" these cases—that is, gives false negatives. In only two cases, both admitting of doubt, from the incompleteness of the Kahn in one and of the Wassermann in the other, did a positive Kahn accompany a positive Wassermann and the Hinton "miss." *Tables I and II, unfortunately, are not comparable on* these points, as the Kahn was not performed in quite a proportion of the interesting cases.

With regard to our modification of the Hinton test, we may note that the 4 per cent. NaCl-glycerol indicator was applied to 114 specimens simultaneously with Hinton's "two-strength" indicator, and a greater sensitivity was observed in practically every one of the 36 positives. There were no qualitative differences, save that in two cases with a marked pseudo-reaction *in the original Hinton test* we obtained a slighter and more easily recognized and discounted reaction with the 4 per cent. suspension.

Our larger series includes 45 cerebro-spinal fluids which give the following comparison:

TABLE VI.

	Hinton Test.	Wassermann Test.
36 cases	negative	negative
1 case	positive	positive
1 ,, ...	weak positive	positive
1 ,, ...	positive	weak positive
1 ,, ...	negative	weak positive
3 cases	negative	positive
2 ,, ...	positive	negative

These few cases rather suggest that the Hinton test is not quite so sensitive with cerebro-spinal fluids, especially as the serums from two of the three cases with positive Wassermann and negative Hinton reactions gave a positive with both tests. The same is true of both of the weakly positive Wassermann reactions. Concerning this point we hope to furnish further evidence at a later date.

The Kahn test, incidentally, was done on 28 of these cerebro-spinal fluids (without the preliminary "concentration" advocated by Kahn), without a single positive result, although including one with both Wassermann and Hinton positive, and two with positive Wassermann and negative Hinton, and one weakly positive Wassermann and negative Hinton, and one with positive Hinton and negative Wassermann. Kahn advocates a preliminary concentration of the precipitating factor in cerebro-spinal fluids by globulin precipitation. Our meagre results would suggest that this is an essential step, and worthy of trial with the Hinton test also.

CONCLUSION.

We have in the Hinton test, especially with the author's slight modification, a very economical, simple, and highly sensitive test for syphilitic serums. There are indications that the test is somewhat more sensitive and more reliable than the Kahn test. It is a further step towards evolving a simple flocculation technique for routine use. We do not hold that the Hinton test is comparable in reliability with a carefully standardized Wassermann technique, such as the Medical Research Committee's No. 4 method, but it would appear to pick out certain types of cases, especially "treated" cases and the controversial "latent" cases, when the Wassermann test at times fails. In the absence of other evidence, however, one cannot feel that a diagnosis of syphilis is to be made on the Hinton (or for that matter any flocculation reaction) alone, whereas a repeated good positive Wassermann reaction does appear to have that significance.

In short the Hinton, like the Kahn, etc., must be reserved as a supplementary test to the Wassermann. It may be used with the same reserve as applies to other flocculation methods: (*a*) where Wassermann facilities are inadequate or not sufficiently organized (for example, in young countries), or (*b*) in hospitals *as a valuable routine on all cases*, to suggest when a further blood sample should be submitted to the central Wassermann laboratory. Difficulties with pseudo-reactions and false positives still weigh against its use by the general practitioner removed from the convenience of a handy serological laboratory.

We desire to express our appreciation of the interest and advice of Professor William Campbell, through whose courtesy we are enabled to publish these investigations.

THE CERVICAL SYMPATHETIC AND ITS RELATION TO THE THYROID GLAND IN EXOPHTHALMIC GOITRE.

BY

R. CUNLIFFE SHAW, F.R.C.S.Eng.,

MANCHESTER.

In this country theories as to the causation of exophthalmic goitre have principally been focused on the thyroid gland, and as a result of such hypothetical basis for the disease operative treatment has been almost entirely directed towards this structure. On the other hand, a very cursory review of the literature of the etiology of this disease, especially from Continental and American sources, demonstrates the fact that in the minds of a very large proportion of investigators an explanation based on a morbid change in the thyroid alone is inadequate to account for the complex phenomena of the disease, and accordingly many theories have been propounded introducing a neurogenic or toxico-neurogenic factor.

Surgery has followed up this reasoning by attempting to effect a cure through extirpation of presumably diseased nervous pathways of the cervical sympathetic system. What, briefly, are the results of surgical intervention directed towards two totally different anatomical structures? Since the commencement of the present century a large series of operations for exophthalmic goitre have been carried out both on the sympathetic and the thyroid; and the outcome of both procedures has been a reasonable proportion of absolute cures or of cases where there has been pronounced amelioration of the symptoms. In order to exemplify briefly this point the following observations may be cited.

Chaîier in 1926 reported a series of nineteen cases of cervical sympathectomy for toxic goitre. The end-results will be seen from the following table.

Cured	3
Greatly improved	9
Slightly improved	6
Recurring	1

During the past few months I selected at random a series of eleven cases of exophthalmic goitre all of which had undergone partial thyroidectomy or ligation of the thyroid vessels, and visited the patients personally in their homes. Their condition as shown in the table below is assessed on such cardinal symptoms as exophthalmos, tremor, pulse rate, nervous irritability, digestion, weight, and general well-being.

Cured (7 years 1; 3 years 1; 2 years 1; 1 year 1*)	4
Unchanged (5 years 1*; 2 years 1; 1 year 1; 6 months 1*)	4
Improved (1 year 1; 9 months 1)	2
Dead (four years later from phthisis)	1

An asterisk indicates that the patients had undergone ligation.
The patient who died showed no improvement before death.

Allowing for spontaneous cures one absolute fact emerges, and that is that the syndrome of exophthalmic goitre can be definitely relieved or absolutely cured by either (*a*) extirpation of a considerable portion of the thyroid gland, or (*b*) excision of the right and left superior cervical sympathetic ganglia and as much of the cervical sympathetic cord as will embrace the variably present middle ganglion.

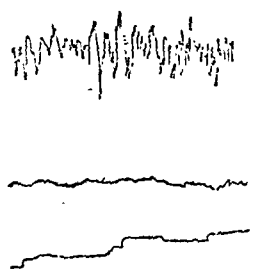
The preliminary results of an investigation of the neuro-glandular etiological relations may now be discussed under two headings—clinical and anatomical.

CLINICAL.

Two cases of exophthalmic goitre have been subjected to the operation of cervical sympathectomy, and in each case there was an exhaustive examination before and after operation.

CASE I.

A woman, aged 62½ years, was taken ill in 1921 with asthenia and palpitation. A few months later exophthalmos developed, and enlargement of the thyroid gland was noticed by her friends. It was further observed that the gland varied in size from time to time; when it was especially prominent the neck was painful. Despite medicinal treatment her condition deteriorated, and she was admitted to hospital on June 8th, 1926. On admission she presented a nervous and emaciated appearance; she weighed 99 lb. The thyroid gland showed diffuse hypertrophy of right and left lobes, with a small adenoma of the isthmus. Exophthalmos was bilateral, and was present to a marked degree; measurement of the globar projection on the micrometer scale was 50 + 2. The pronounced tremor of both hands is indicated in the accompanying illustration. The basal metabolic rate determined by the Douglas bag and Haldane apparatus was + 44 per cent. (The patient had been many weeks in bed, and samples were collected after twelve-hour fasts.) In the adrenaline tolerance test 5 *mm.* of 1 *in 1,000* solution produced a rise of brachial pressure of 2 mm. of mercury and 43 beats per minute.



Heart.—Severe auricular fibrillation was present; the apex beat was highly irregular. There was no bruit; the pulse rate was 104 per minute.

Electro-cardiograph.—Lead I: Extrasystoles, R.V., 1. Lead II: Rate, A. 480; V. 120. Rhythm irregular.

Bowels frequency:			
Day (6 a.m. to 10 p.m.)	1	1	1
Night (10 p.m. to 6 a.m.)	0	0	0
Micturition frequency:			
Day	5	6	5
Night	1	1	1

The knee-jerks were very sluggish. Pressure pain over the thenar region was produced by 2.5 kilos.

The patient was treated by x rays and digitalis, but the result was negligible, and there was pronounced increase of the nervous instability. At an operation on August 21st, 1926, the right and left superior cervical sympathetic ganglia and both cervical cords as far as the inferior ganglia were excised. The operation was conducted under gas and oxygen anæsthesia; there was a rise of the radial pulse of 6 per minute; both pupils were contracted, and enophthalmos was easily observed.

During the first few days after operation there was severe auricular fibrillation, which was controlled by digitalis. The exophthalmos steadily returned to the pre-operative condition. The micrometer reading was 50, and after seven days the basal metabolic rate was reduced by 13 per cent. The tremor showed decided diminution in frequency and amplitude of cycles. Neck measurements before and after the operation were as follows:

	August 26th.	September 28th.
Trans-cricoid plane	30 cm.	30 cm.
Mid-crico-manubrial plane ...	32 ,, ...	31 ,,
Supramanubrial plane	34 ,, ...	33 ,,

The pressure pain and adrenaline tolerance were unchanged.

Re-examination, August 27th, 1927.—Her condition shows a steady improvement up to this date; she has gained in weight and feels stronger. The exophthalmos has slightly improved, tremor is practically negligible except when overtired or worried. Prior to operation her writing was illegible; it is now clear with no suggestion of vibration. Pulse 80 to 90; she still has attacks of palpitation. The thyroid shows no change in the size of the lateral lobes. The adenoma has now become cystic and slightly larger.

Re-examination, May 25th, 1928.—She has had a recent attack of influenza and much mental worry. Tremor has returned within the past fourteen days; her handwriting is legible though extremely shaky; the weight has considerably decreased, the radial pulse is 90 per minute; heart-beat very irregular; neck measurements show a pronounced diminution in the size of the thyroid: circumferences were as follows: trans-cricoid plane 28 cm.: mid-crico-manubrial plane 30 cm.: supramanubrial plane 33 cm.

Exophthalmos was still very pronounced, and certainly more so than on the last previous visit.

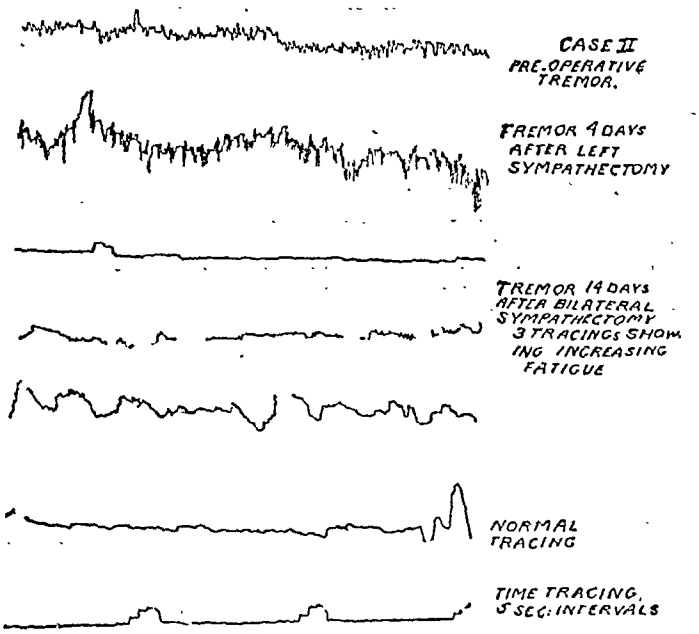
CASE II.

A man, aged 31, with a history of cyclical nervous instability, with early onset of hand tremor, loss of weight, and nervous irritability. Three years after the appearance of the initial symptoms enlargement of the thyroid gland was noted. Eighteen months later exophthalmos developed, and six months after this severe attacks of palpitation occurred. On December 8th, 1927, the right and left superior thyroid vessels were ligatured: iodine was administered and the patient was sent home on December 18th. Following this he lost 23 lb. in six weeks during a severe exacerbation of all the symptoms. He was readmitted to hospital on January 30th, 1928. On examination he weighed 7 st. 4½ lb. (his normal weight was 11 st.). Exophthalmos was present in both eyes, principally due to pronounced spastic retraction of the eyelids, especially the outer part of the superior lid; there was slight oedema of the lower lids. There was diffuse enlargement of the entire thyroid gland; it was pulsatile with audible bruit.

Circumferences of the neck were as follows: cricoid plane 36 cm.; mid-crico-manubrial plane 40 cm.; supramanubrial plane 43 cm.

The tremor was of the rapid fibrillary type with a rhythm of eight cycles per second. There was slight dilatation of the right side of the heart and auricular fibrillation. Pulse 101. The basal metabolic rate, estimated by the Douglas bag and Haldane apparatus, was + 75 per cent. Pressure pain was 10.5 kilos over the thenar region. In the adrenaline tolerance test 5 mm. of a 1 in 1,000 dilution produced a rise of 25 mm. of mercury in the blood pressure and an increase of pulse rate to 112. There was a generalized faint pigmentation and alopecia of the face and scalp. His bowels acted twice during the day and not at all in the night, and he passed water two to four times in the daytime.

On February 29th *resection of the left cervical sympathetic cord was performed without disturbing the ganglia.* Immediately after the operation there was a pronounced increase in tremor and rhythmical motion of the whole arm, with a frequency of three cycles in five seconds. The hand tremor increased ten cycles per second. The exophthalmos was unchanged. There was hyperidrosis of the right side of the face; the left side was dry. Immediately after operation the temperature was 99° F., the pulse 128, and the respirations 24. After five days the corresponding figures were 98.4° F., 118, and 22.



On March 7th, 1928, excision of the right superior sympathetic ganglion and a portion of the cord was performed. Following a transitory febrile period due to tonsillitis the hand tremor subsided markedly, the recording lever remaining stationary for considerable intervals, with an occasional slow rhythm of four or five cycles per five seconds. There was pronounced diminution in the spastic retraction of the eyelids.

On March 20th the basal metabolic rate was + 32 per cent., a fall of about 40 per cent. The adrenaline tolerance test showed a rise of blood pressure of 10 mm. of mercury, with no increase in the pulse rate. The pressure pain figure on the right side was 9 kilos; on the left 8 kilos.

Re-examination, May 23rd, 1928.—The patient appeared to be very well and had gained weight; on May 14th he weighed 8 st. 4 lb. Hand tremor was negligible. The exophthalmic appearance was greatly improved. He had no attacks of palpitation; pulse rate 88.

From a study of the data of the foregoing cases the following points may be deduced.

1. That in cases of exophthalmic goitre extirpation of the *cervical sympathetic ganglia has a threefold effect on the* syndrome of the disease: (*a*) an immediate phase of increase in all the symptoms, due probably to augmented thyroid activity; (*b*) followed quickly by the first improvement phase, in which there is a considerable fall in the *basal metabolic rate and a diminution of hand tremor*; (*c*) a second improvement phase sets in after a month or more in which there is a general amelioration of all the symptoms. It is the variability of the degree to which this latter improvement progresses that determines the question of ultimate success of the operation.

2. The effect of sympathectomy on the exophthalmic appearance is apparently uncertain. If the appearance is due to spastic retraction of the eyelids as in Case ii, then sympathectomy effects an improvement. On the other hand, where the appearance is due to the projection of the ocular globe as a whole sympathectomy has little or no effect. It is interesting to note here an observation made *post mortem* on an exophthalmic eye. After death there was still decided ocular prominence, and incision of the conjunctiva and examination of the orbital contents showed the forward displacement to be due entirely to the accumulation of a considerable quantity of clear fluid.

3. The effect of sympathectomy on the thyroid gland in Case i produced post-operative increase in the size of the adenoma and shrinkage and atrophy after some months. In Case ii the size and tension of the thyroid diminished from the onset of the first improvement phase.

Floresco, Missirolli, and Wiener found that section of the cervical sympathetic excited transitory thyroid hyperfunction, followed by rapid atrophy of the thyroid gland, an observation which provides us with an explanation of the post-operative crises and the changes in the size of the thyroid.

4. In weighing the foregoing results it will be remembered that Case i had had prolonged radiation and Case ii ligation of the superior thyroid vessels, and both had undergone a course of iodine treatment, the results of which procedures had been negligible at the time of sympathectomy, at which period they were judged grave operative risks. The *inadequate ultimate results in Case i* led to a closer investigation of the anatomical connexions between the sympathetic and the thyroid glands.

5. In each case histological examination of the extirpated ganglia revealed the following changes: granular *degeneration or atrophy of the nerve cells, increase of* connective tissue, and hyperpigmentation comparable to the changes described by Wilson and Durante of the Mayo Clinic.

In conclusion a few words may be added as to the *practical aspects of the sympathetic operations for this* disease. As far as one can say at present they are not a cure, but nevertheless, if successfully carried out, they produce a very considerable improvement. This amelioration is considerably greater than that obtained by ligaturing the blood vessels, and since the technique is no more difficult, and the risks are not more hazardous, it seems a reasonable proposition to undertake it in cases where the symptoms are of such a degree of severity as would contraindicate a partial lobectomy, thereby obtaining a margin of improvement which would permit this operation to be performed at a later stage.

Again, this operation would appear to be eminently suitable in cases where the cardiac derangement is too serious to allow any thyroid operation to be contemplated, and where the thyro-toxic symptoms are progressive despite medicinal treatment and therefore endanger life, as in Case i.

ANATOMICAL.

According to Berkeley, Crissafulli, and Rhinehart, and further quoted by Wilson and Durante, the superior and middle cervical sympathetic ganglia furnish the entire nerve supply to the thyroid gland.

It is obvious that if this statement is accepted the operation of sympathectomy need only embrace these two ganglia *on both sides in order to effect a complete denervation of* the gland. Such is the operation usually practised, and such was the technique in the cases investigated personally. The measure of success for this procedure has been fully discussed; that this should be incomplete at once suggests an *inadequate denervation*, hence a most careful investigation of the nerve supply from the inferior cervical ganglion has been carried out.

In all, six adult bodies and five *foetuses* have been examined. In every case a communication was found to exist between this ganglion and the thyroid gland on both sides of the neck; it was variable in its position and anatomical course. The following are the chief variations.

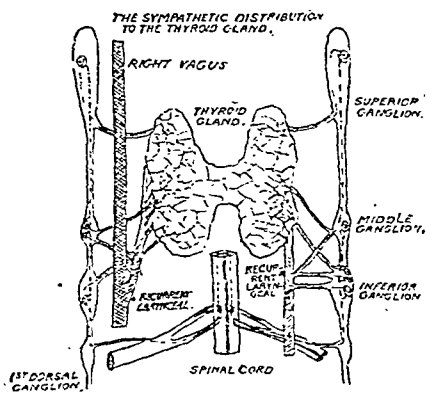
1. The communication may arise either as one or two delicate nerves from the inferior cervical ganglion. On the *left side*, after passing inwards and downwards a short distance, it doubles back along the course of the recurrent laryngeal nerve to be distributed to the postero-inferior aspect of the lower pole of the left lobe of the thyroid. On the *right side* this filament (or filaments) frequently anastomoses with the right recurrent laryngeal nerve at a distance of about 1 to 2 cm. from the origin of the nerve from the vagus, after which the fibre may be traced as a distinct fasciculus on the lower and inner surface of that nerve, and leaves it as a plexus of delicate filaments

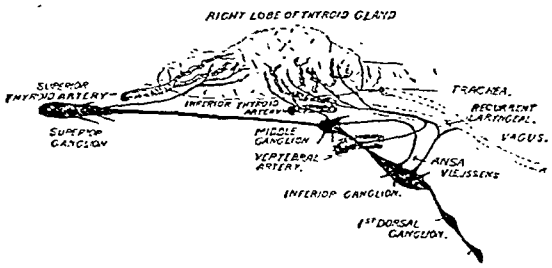
to be distributed to the corresponding aspect of the right lower pole.

2. The communication may arise as a branch from the sympathetic cord between the middle and inferior ganglia, in which case the ultimate distribution is the same as in the previous instance.

3. On the left side there may be several small filaments arising from the inferior and middle cervical ganglia, which pass inwards and downwards closely associated with the vertebral artery and reach the left recurrent nerve, when they are distributed both upwards and downwards in that nerve; those fibres passing towards the head may be partly traced into branches to the thyroid gland.

These communicating fibres to the recurrent laryngeal are indicated in the accompanying illustrations.





Pavlovsky has emphasized the importance of a group of fibres from the inferior cervical ganglion which reach the thyroid along the inferior thyroid arteries. Although in a few instances there were filaments from the middle ganglion accompanying this vessel they were not so constant and definite a feature as that described above.

The practical deduction to be made from the anatomical findings is the importance of extirpation of the middle and inferior cervico-ganglionic section of the sympathetic on at least one side—namely, that on which the thyroid changes are most pronounced. If partial denervation of the gland results in considerable mitigation of the symptoms, then it seems logical to suppose that a similar and still more complete procedure would be correspondingly more effective.

Further, it might be tentatively pointed out that since all the sympathetic supply to the thyroid passes out of the spinal cord at the level of the first and second dorsal segments and traverses the inferior ganglia, it follows that removal of the latter should be equivalent to removal of the entire three ganglia, and would obviate a more extensive operation.

DELAYED CORNEAL ULCERATION FROM MUSTARD GAS.

BY

R. FOSTER MOORE, F.R.C.S.,
OPHTHALMIC SURGEON, ST. BARTHOLOMEW'S HOSPITAL,
AND
FRANK HECKFORD, M.R.C.S., L.R.C.P.

THE two following cases which have come under our notice seem sufficiently important to be placed on record, and this for two reasons: first, because of their intrinsic clinical interest, and secondly, because of their specific importance from the point of view of war pensions. One of us has seen both cases, and so is able to be sure of the essential similarity between them.

We wish to emphasize that these ulcers have features which are so characteristic as to render them almost pathognomonic, and there should be no fear, therefore, of false claims being made for pensions on account of ordinary corneal ulcers.

The history of the two cases is as follows.

CASE I.

A medical man was attacked by mustard gas in 1917, and is in receipt of a pension for defective sight of the left eye from corneal nebulae resulting from ulceration in 1922. The right cornea was unaffected until May 7th, 1928—that is, eleven years after the gassing. It then spontaneously became ulcerated at a point downwards and to the nasal side. The ulcer at first was small, but afterwards enlarged so as to involve more than one-third of the area of the cornea. From the first it was deep and crater-like at its centre, extending down to Descemet's membrane. For many weeks it seemed that it would perforate at this spot; but this did not happen, and it ultimately healed over. In the substance of the cornea were grey lines of infiltration radiating more or less from the borders of the ulcer; a small area only was stained by fluorescein.

On curetting, the surface epithelium of the cornea was found to be sodden and ill nourished for a considerable area around; it easily separated, leaving a large bare surface. The substantia propria was infiltrated in such a way as to produce a sort of cleft in its substance in a plane parallel with the surface. The ocular conjunctiva exhibited the appearance, to be referred to later, which is characteristic of these cases. (Fig. 1, C, Fig. 2, D.)

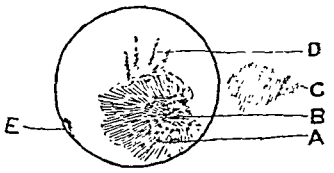

FIG. 1.

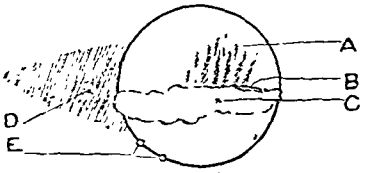

FIG. 2.

Some iritis developed, but it was very mild in degree, and called no trouble; the left eye remained quiescent throughout. There was never any very acute reaction in the eye, and photophobia was less marked than would have occurred from an ordinary ulcer. The general appearance was that of a slowly spreading, very indolent ulcer, of which a small part only stained; corneal infiltration extended in advance of the ulceration, which gradually spread so as to invade the pupillary area, producing considerable defect of vision, which necessarily is permanent.

At the end of five months it seemed that the extension of the ulcer had stopped. The clear point where Descemet's membrane had been exposed was becoming healed and the excavation gradually filling in. This progress has continued up to date; repair, however, is even now, at the end of seven months, by no means complete.

CASE II.

A healthy man, aged 38, when first seen by one of us gave the following history. He had suffered badly from mustard gas burns in the usual parts of the body, including the eyes, in July, 1917;

he was invalided as a consequence, and written down as B 2. From that time to the present he has been bothered at intervals by bright lights, but otherwise has had no particular trouble until July, 1928, when both corneae developed small deep ulcers, which showed little staining with fluorescein. Since then his trouble has slowly progressed, until on November 22nd, 1928, the condition of the eyes was as follows.

Extending across the cornea of the right eye from side to side, and beyond it on each side, invading the sclera for a short distance, was a deep, gutter-like excavation of the corneal tissue (Fig. 2, C). The edges had a somewhat rolled appearance, and at the situation B, Fig. 2, were sodden-looking and stained on instilling fluorescein; the remaining area did not stain. Above the ulcer, in the situation A, Fig. 2, was a greyish, somewhat linear infiltration of the cornea, and at E were two small punched-out circular ulcers. The conjunctiva over the area D, Fig. 2, was opaque white, and marbled in appearance, as described later.

The condition of the left eye was in all essentials similar to the right, but ulceration was not so extensive. There was the same gutter-like excavation affecting the part of the cornea exposed in the palpebral fissure. It extended rather more than half-way across the cornea, and involved the adjoining corneo-scleral junction; a small spot only stained. The conjunctiva showed the same scarred appearance, and there was no intraocular involvement.

It may at once be stated that all the eyes had essentially similar features, though differing in detail, and were clearly similar to the case published by Mr. Humphrey Neame in the *Transactions* of the Royal Society of Medicine in November, 1928.

We may now examine the special features of these ulcers. First the intolerance of light is much less marked than might have been expected from the extent of the ulcer, and the circumcorneal injection of the eyes was less than would be present in other forms of corneal ulcer of similar dimensions in patients of this age. The ulcers themselves showed a marked tendency to involve the parts exposed in the palpebral aperture—that is, of course, the part originally exposed to the gas. They were deeply excavated, had a gouged-out appearance, and the tissue at the edge appeared sodden and ill nourished. They extended deeply into the substantia propria—so deeply, in fact, as to expose Descemet's membrane in Case i. They did not, however, perforate. In general appearance they reminded one a little of a Mooren's ulcer. The instillation of fluorescein did not produce extensive staining, but only showed up small spots or areas, chiefly at the edges.

From the shelving side of the ulcers infiltration could be seen extending into the adjoining cornea, and showed up as a grey area in it which had a linear arrangement (Fig. 1, D, Fig. 2, A). In one case iritis was present, but it was quite mild, and this in spite of the long persistence of the condition. In both of our cases, as well as in Neame's, one or two small localized, deep, nearly circular ulcers developed at the limbus (Figs. 1 and 2, E).

A marked feature of the ulcers was the long period, roughly ten years, between what clearly was their ultimate cause and their actual development; their extreme indolence; their situation in the palpebral aperture; their deep, gouged-out appearance; the comparatively mild symptoms; and their slow healing. The conjunctiva within the palpebral aperture has a very characteristic appearance, and even now is a good deal reminiscent of its appearance at the time of the gassing. It is somewhat swollen and in parts is almost of a homogeneous pearly white colour; in other parts, where it is less opaque, it has a marbled appearance, the "veining" effect being produced by the vessels, which in places show great irregularity in their calibre. It seems reasonable to suggest that it was the damage done to the vascular and nerve supply of the cornea by the gas, and the subsequent scarring, which has resulted in permanent impairment of the nutrition of the cornea and so to its ultimate ulceration.

With regard to treatment, we believe the most help is to be obtained from curetting any staining area, and cauterizing this small point very carefully with carbolic, or with the actual cautery. We have tried many other drugs without any clear advantage. We seriously contemplated sewing the lids together, and are inclined to believe, like Mr. Herbert Fisher, that this would prove valuable. We doubt whether any form of corneal section is advisable.

NINE CASES OF ERYTHEMA NODOSUM.

BY

R. HUGHES PARRY, M.B., B.S.LOND., D.P.H.,

CHIEF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT TUBERCULOSIS MEDICAL OFFICER OF HEALTH, BRISTOL;

AND

E. JOAN PARRY, M.R.C.S.,

FORMERLY CLINICAL ASSISTANT, ST. JOHN'S HOSPITAL FOR SKIN DISEASES, LEICESTER SQUARE, LONDON.

DURING the winter of 1926 and spring of 1927 nine cases of erythema nodosum came under our notice in a busy country general practice. A short account of these cases may not be uninteresting as throwing some light upon the etiology of the condition.

Case 1.—A single woman, aged 23, first came under our notice with complete blindness in the right eye. She was sent to hospital to see a consultant, who reported to us that she was suffering from a retrobulbar neuritis of rheumatic origin. She was given salicylates internally and made a complete recovery in two months. She resumed her duties, but eight months later complained of pains in her limbs. On examination it was found that she had developed well-marked erythema nodosum, but had no signs or symptoms of rheumatism. Under our usual treatment—namely, sodium salicylate internally and liniment of methyl salicylate locally—she made a complete recovery within a fortnight.

Case 2.—We were called in to see this patient, a youth, aged 17, after he had been in bed with pyrexia for two days. For a further four days he remained feverish, but there was no other sign or symptom and a diagnosis could not be reached. The pyrexia did not respond to quinine treatment. On the seventh day of the fever he was given the following mixture every four hours.

Sod. salicyl.	gr. vij
Liq. ammon. acetas	℥i
Spirit. chlorof.	ɱvij
Aq. camph. ... ... ad	℥ss

Twenty-four hours later his temperature started falling, and coincidently with this erythema nodosum appeared on both legs causing much local pain and tenderness. Local application of liniment of methyl salicylate relieved the pain and the patient made an uneventful recovery. Apart from some asthma and a nasal catarrhal condition this patient had always been well. His mother was also slightly asthmatic, but the rest of the family—father and two brothers—were very strong and healthy.

Case 3.—A farm labourer, aged 37, reported with typical erythema nodosum on both legs. He declared that he felt perfectly well, but the "lumps" on his legs were somewhat tender to pressure, and his legs generally ached. His temperature and pulse were normal. He was sent home to bed and given the usual antirheumatic treatment. The following day we were summoned urgently to see the patient, and found him with a temperature of 101°, a rapid pulse, and feeling very sorry for himself. He had been feverish all night. A thorough examination revealed nothing more than the nodules on the legs. Within a further twenty-four hours the temperature and pulse had returned to normal, the nodules became smaller, and the patient recovered. He has been perfectly well for the last two years. The patient had been a healthy man until this illness, but it is interesting that one sister has since come under our care for pulmonary tuberculosis and has recently been discharged from sanatorium, and a brother was given three months' leave for chronic cough and doubtful signs in the chest.

Case 4.—The patient was a schoolgirl, aged 15. We were called upon to visit her father, a farmer, aged 47, who had always been a particularly strong and healthy man, but for the previous week he had suffered from a short dry cough, marked shortness of breath, and some cyanosis. The diagnosis of rheumatic pleurisy with pericarditis was later verified by his response to treatment and he made a complete recovery. Casually we were asked to look at the girl's legs because she had been complaining of pain in them since the previous day. She had well-marked nodules on both legs with some pyrexia and sweating. Under antirheumatic treatment she recovered rapidly.

Case 5.—This patient, a woman aged 42, consulted us for "painful lumps" in both legs, diagnosed as a typical erythema nodosum. The usual treatment was prescribed. Three days later we were summoned to see her as she was worse. To our surprise we found her legs were more tender and inflamed. On further inquiry it was discovered that the dispenser had given her methyl soap liniment instead of liniment of methyl salicylate. She obtained immediate relief with the latter liniment, but it took three weeks before the nodules completely disappeared with the pain. It is interesting to note that about fifteen months previously we had attended her only son for acute rheumatic arthritis, and he had been under our treatment for three months.

Case 6.—A woman, aged 45, consulted us with erythema nodosum of both legs. She felt a little run down and out of sorts, and complained of tenderness of the legs, but her temperature was normal, and apart from well-defined nodules on her legs nothing abnormal was found on examination. She was placed on the ordinary treatment. She was seen twice again; on the

occasion she reported herself as free from trouble with her legs, and asked for a tonic. The patient declared that she had derived much relief from the local application of methyl salicylate ointment.

Case 7.—A married woman, aged 55, consulted us for "tender lumps on her legs." She complained of not feeling well, but, apart from slight anaemia and the condition of her legs, she appeared to us to be quite well. Our usual treatment was prescribed, and when she reported again in a week's time she was much improved.

Case 8.—This patient, a married woman aged 65, was under our treatment for heart trouble—aortic and mitral regurgitation. On this occasion she suddenly fell ill, with a temperature of 102° and a rapid irregular pulse. After four days of irregular pyrexia she apparently improved, the temperature returning to normal, but her pulse remaining somewhat irregular. Two days later—on the seventh day of her illness—she developed erythema nodosum, first in the left leg and later in the right leg. She could not tolerate salicylates, and it was many weeks before the nodules disappeared from her legs. The patient recovered from this attack, but died about nine months later from heart failure.

Case 9.—An unmarried woman, aged 22, reported with erythema nodosum in one leg only, much debility and anaemia, but no fever. She found great relief in the local application of methyl salicylate ointment. Finally, she made a complete recovery, but the marked debility and anaemia persisted for several weeks. We attended this patient subsequently on two occasions for erythema pernio, which responded to treatment with calcium lactate.

The series obviously is too short to warrant any final conclusions, but we could not help being struck by the following facts:

1. In four cases only were we able to detect pyrexia (Cases 2, 3, 4, and 8). In two cases the nodules on the legs apparently were present before the pyrexia (Cases 3 and 4); in the other two cases (2 and 8) the fever had abated before the nodules appeared.

2. The close association in two cases (4 and 5) between a family history of acute rheumatism and erythema nodosum. In two of the cases (1 and 8) there had been a definite attack of acute rheumatism.

3. In every case marked relief to the tenderness in the legs was obtained by the local application of methyl salicylate, either as the liniment or as the ointment.

4. Internal administration of sodium salicylate definitely did appear to have a beneficial effect, and intolerance to the drug was accompanied by the prolonged course of the condition (Case 8).

5. The families of all these patients are well known to us, and in no instance, except Case 3, was there a past history of tuberculosis.

THE USE OF HEROIN AFTER ABDOMINAL OPERATIONS: A WARNING.

BY

A. E. MORTIMER WOOLF, F.R.C.S.,

SURGEON, QUEEN MARY'S HOSPITAL FOR THE EAST END; SENIOR SURGEON, EAST HAM MEMORIAL HOSPITAL.

THE relief of pain after an abdominal operation is not infrequently one of the first cares of the surgeon, and for this purpose the injection of morphine or heroin is often necessary. For some years, in common, I believe, with many surgeons, I have favoured heroin rather than morphine. My reasons are shortly as follows: (1) heroin is more effective as an analgesic than morphine; (2) it has less after-effect as regards distension, constipation, and general malaise; (3) if a tube of morphine has been kept for some little time a change into apomorphine may occur, with resulting vomiting.

For a good many years, both in hospital and in private practice, when necessary 1/6 grain of heroin has been administered without the slightest ill effect. The following two cases are cited, however, as a warning.

CASE I.

A lady, 64 years of age, rather asthmatic, suffered from chronic cholecystitis. Owing to the asthma, in order to give as little anaesthetic as possible, 1/4 grain of morphine together with 1/100 grain of atropine was administered half an hour before operation, but it was done purposely for the reasons mentioned above.

The operation consisted of a cholecystectomy, and the anaesthetic was gas and oxygen and warmed ether. The operation was completed in forty-five minutes, and the patient was back in bed at about 10 a.m. At 1 p.m. I saw her, when she was well round, and complaining of a lot of pain. She was sufficiently conscious to be asking for her artificial teeth. As she seemed to be in great pain I ordered 1/6 grain of heroin, which was administered just after 1 o'clock. At 1.25 I received a telephone message to come round to the nursing home at once. The injection had relieved the pain within five or six minutes, and the matron had left the room, but thought that she would go in and see her again after about ten minutes. On going into the room the patient was talking, when suddenly she became quiet and the matron noticed a change in her breathing. She immediately realized that the patient was profoundly unconscious, administered strychnine, brandy, and ether hypodermically, and sent for me. When I arrived the patient was blue, the skin was mottled, and she was breathing about once in every two and a half minutes; but the pupils were not pin-point, and never were during the whole course of events. The pulse was good, about 80. I immediately thought of internal haemorrhage and of a possible embolism, but obviously neither of these catastrophes had occurred.

At the time I was in the dark as to the cause of the patient's condition, and although it occurred shortly after the administration of the heroin, I did not believe this to be the cause. The patient was literally *in extremis*. The tongue was pulled out, the mattress turned round, and artificial respiration commenced. Owing to the conformity of the chest the greatest difficulty was experienced in forcing inspiration, and all that seemed possible to do was to empty the chest of air.—A voluntary breath was taken about once every two minutes. After a short time I sent for Dr. R. J. Clausen, who had administered the anaesthetic, with the intention of possibly inflating the lungs through a laryngeal tube. Pending his arrival, artificial respiration was maintained. Dr. Clausen considered that it would be inadvisable to pass a laryngeal tube, and tried to stimulate inspiration by the administration of carbon dioxide. This, however, did not meet with any success.

After about an hour the respirations seemed to be rather better. The patient was now breathing about once every minute, and it was then noticed that if artificial respiration was stopped the pulse began to flag. After about an hour and a half the respirations approximated two to the minute, and the first sign of hope appeared—namely, the coffee which had previously been administered per rectum was returned. Just about this time a few involuntary faeces movements were noticed, and artificial respiration could be left off for a short while. After about two hours I noticed that the inspiratory movement of artificial respiration stimulated a voluntary respiration, but that without artificial respiration only two to three respirations a minute were voluntarily performed. At the end of three hours there were definite signs of returning consciousness, and a conjunctival reflex was occasionally obtained when artificial respiration was continued. On ceasing the artificial respiration the reflex disappeared.

At this time I realized that the breathing was that of a profoundly drugged person, similar to what I had seen in morphine poisoning. It was necessary to continue intermittent artificial respiration for another hour, care being taken that the artificial inspiratory movement did not stifle a voluntary expiratory effort, and vice versa. At 6 p.m. respirations were about five to the minute, and the need for artificial respiration no longer existed. At 6.30 the patient recovered consciousness—that is, after five and a half hours.

The following morning respirations were ten to the minute. Convalescence after this was uneventful, except for considerable pain in the right arm, which had been dislocated during the movements of artificial respiration. This necessitated another anaesthetic for replacing the joint by Kocher's method.

The tube of heroin tablets (1/6 grain) was subsequently investigated. It was not a new tube, and tablets had already been administered to other patients without ill effect.

While the patient was convalescent I vaccinated the right arm with 1/6 grain of heroin dissolved in water, and vaccinated the left arm with a normal saline to act as a control, in order to see if a possible idiosyncrasy for heroin existed. No difference between the two sides could be detected. It is, of course, possible that a desensitizing effect may have been produced, though this is very unlikely.

CASE II.

The second case, for particulars of which I am indebted to Mr. W. E. Tanner, was that of a patient, aged 49, on whom cholecystectomy and appendicectomy had been performed. Before the operation 1/100 grain of atropine was given, and the anaesthetic was open ether. About an hour after the patient had been put back to bed 1/6 grain of heroin was given hypodermically. The patient became comatose, with pin-point pupils and no conjunctival reflex. The respirations fell to three a minute, the pulse to 60. She was given pituitary extract and strychnine, and artificial respiration was carried out.

Five hours after the injection of heroin the respirations were nine to the minute. The patient was drowsy, but could be roused. Fifteen hours later the patient was fully conscious; the respirations were eighteen to the minute, and she made an uninterrupted recovery.

CONCLUSIONS.

I have thought it well to put these two cases on record to serve as a warning. Respiratory stoppage must be very rare, but nevertheless when it does occur the very alarming situation can scarcely be imagined.

It is interesting that both these cases were cholecystectomies. In the one case morphine had been given prior to the operation, but not in the other. On the other hand,

the case which had had no morphine prior to the operation had had the heroin administered much sooner than in the first case. Since this episode, which nearly ended in a catastrophe, my practice has been (1) to be quite sure that the patient is fully round from the anaesthetic before any hypodermic injection is administered, and (2) to give only 1/12 grain of heroin, and to repeat it if necessary. My preference for heroin over morphine is still very strong; but the above two cases show that its effect on the respiratory centre may be exceedingly dangerous unless it is given in small doses. It is to draw attention to this fact that I have thought it advisable to publish these two cases.

THREE CASES OF VOLVULUS OF THE SIGMOID FLEXURE OF THE COLON.

BY

W. GIFFORD NASH, F.R.C.S.,

SURGEON, BEDFORD COUNTY HOSPITAL.

IN the first half of 1928 three cases of intestinal obstruction due to volvulus of the sigmoid flexure of the colon came under my care and recovered after operation.

CASE I.

A woman, aged 45, was admitted to the Bedford County Hospital on January 6th, 1928, suffering from extreme abdominal distension, severe pain, and great difficulty of breathing. She gave a long-standing history of constipation, sometimes getting no action of the bowels for three weeks. For three years she had been liable to attacks of abdominal pain, but had never vomited. The history of the present attack was absolute constipation for five days, abdominal pain for two days, retching but no vomiting, and great difficulty in breathing.

On admission to hospital the abdomen was greatly distended, no movement was visible, and there was tenderness in the lower abdomen, especially on the left side.

Operation.—The abdomen was opened in the middle line, and a large quantity of stinking blood-stained fluid escaped. A large cyst-like swelling presented, filling the pelvis, extending well above the umbilicus, and measuring ten or twelve inches vertically. This swelling was black in colour, resonant, and evidently was gangrenous bowel. It was too large to extract through the incision, so was punctured with a large trocar, giving vent to horribly fetid gas. The gangrenous bowel was then delivered from the abdomen, and a piece about eighteen inches long was found to be twisted. This was resected, and the ends of healthy bowel were brought out of the wound and tubes tied in. The cut ends of healthy gut were fixed to one another and to the edges of the peritoneum. When the patient recovered from the anaesthetic her first remark was that she could breathe freely.

The colostomy acted three days later. On February 20th the spur between the divided ends of bowel was crushed by an enterotome, and came away on March 2nd.

She left the hospital on April 23rd with a small sinus. When last seen, on October 19th, there was a pinhole aperture from which a little gas escaped; her bowels were acting well, she had grown stout, and was in perfect health. After the operation *x*-ray examinations with a barium meal and enema showed that the part of bowel removed consisted of sigmoid flexure and pelvic colon.

CASE II.

A lady, aged 19, pupil at a physical training college, was taken ill at 4 a.m. on May 27th, 1928, with abdominal pain situated chiefly under the left costal margin and in the left loin. She did not vomit, and there was no rise of temperature. Enemata were given without result, and no flatus was passed. These symptoms continued until I saw her on May 28th, at 7 p.m. There was then slight distension of the abdomen, and the chief pain was in the left upper quadrant. There was considerable difficulty of breathing. Morphine and atropine were given, as it was thought the symptoms might be due to enterospasm.

On May 29th there was no improvement, and she was admitted to a nursing home for operation. A subumbilical median incision was made, and the sigmoid flexure of the colon was found to be enormously distended, twisted, and [illegible]sured about six inches in diameter, and pressed [illegible] The gangrenous bowel was brought out [illegible]d resected. Tubes were tied in the cut ends.

On June 2nd, as the abdomen remained distended and there was no discharge from the colostomy, a caecostomy was performed, and 25 c.cm. of *B. welchii* serum was given. Ten days later the caecostomy closed, and on July 1st the patient got up.

On July 11th an enterotome was inserted to crush the spur between the divided ends of the bowel. The bowels acted naturally on July 18th, and next day the clamp was removed. From this time the opening rapidly closed, the bowels acted daily, and on August 4th she left the nursing home with a minute fistulous opening. On October 30th this had completely closed; the bowels acted daily after a dose of petroleum.

Before the attack of volvulus the patient had been very healthy except that she suffered from constipation, for which she had taken large doses of various aperients.

CASE III.

A gentleman, aged 74, was admitted to a nursing home on June 10th, 1928, suffering from symptoms of intestinal obstruction of three or four days' duration.

Previous History.—In 1917 he suffered from constipation, with pain in the back and chest due to flatulence. In 1919 he had a similar attack. In 1926 he had a worse attack, and was in bed for a month.

On admission to the nursing home he had absolute constipation and no flatus could be passed. Enemata had no effect. He had been vomiting for two days. The abdomen was very distended.

A subumbilical median incision was made and an enormous distension of the pelvic colon and sigmoid flexure was found, due to a twist. Owing to the age of the patient and to the bowel not being gangrenous resection was thought to be contra-indicated. After untwisting the bowel an opening was made near the lower end of the volvulus and a large tube inserted. This gave some relief, but the abdomen remained distended. At the operation 25 c.cm. of *B. welchii* serum was given.

On June 16th caecostomy was performed. This was followed by acute gastric dilatation, manifested by great swelling over the stomach and persistent vomiting. The viscus was washed out two or three times a day for three days, and saline enemata, pituitrin, and strychnine were administered.

He gradually improved, and the caecostomy and colostomy openings discharged freely. He gradually regained health and strength, and, except for the bowel acting through the colostomy, may be considered to have regained his normal health.

Remarks.

The interest of these cases lies in the fact that they all recovered, that they occurred within six months, and are the only cases of volvulus I have met with in a period of over thirty years' work as surgeon to a hospital.

THE SAFETY OF ETHYL CHLORIDE, AND THE POSITION OF THE PATIENT DURING GENERAL ANAESTHESIA.

BY

R. W. HORNABROOK, M.B., B.S.,

ANAESTHETIST, MELBOURNE HOSPITAL.

AT a coroner's inquiry into a recent death under ethyl chloride in Melbourne the question was raised as to the safety of ethyl chloride as an anaesthetic. Like every other anaesthetic, there is a risk in its administration under certain conditions, especially by the closed method—that is, a method in which air is not admitted to the patient during induction—but given a free supply of air during induction and used in either the open or semi-open method, it is one of the safest of all anaesthetics, not even excepting nitrous oxide and oxygen. The above remarks do not mean that one can be free and easy with it; no anaesthetist at any time can ever be free and easy with any anaesthetic. By the semi-open method the air valve in the inhaler, which should have a diameter of not less than half an inch, is gradually closed over as induction proceeds, so that by the time induction is completed—which is, as a rule, in from one and a half to two and a half minutes—the air valve is fully closed. This will give from three to five minutes' full anaesthesia.

Ethyl chloride is not a drug that should be used for prolonged anaesthesia, nor is it intended that it should so be used, except under very exceptional circumstances, and in the hands of an expert. This is for two reasons: first, its great cost, and secondly, its wastefulness when used for any length of time by the open method. It is one of the very best of all the anaesthetics we have for short operations of from one to five minutes or for preliminary induction to ether. In using the words "ethyl chloride" I include also somnoform, which is 83 per cent. ethyl chloride, 16 per cent. ethyl bromide, and 1 per cent. methyl bromide. At the Melbourne Dental Hospital and the Melbourne Eye and Ear Hospital it has been used in considerably over 75,000 patients of all ages during the past twenty-three years, and there have been two deaths, one of which I think should not have happened. The collapse occurred during a second administration of ethyl chloride to an exceptionally delicate female patient who had recently had a very severe haemorrhage and was not, in my opinion, a fit subject for the second administration of an anaesthetic, either local or general.

This morning (December 6th), on reading the report of the inquest in the morning papers, I decided to test for myself the so-called dangerous effects of ethyl chloride under what would normally be considered disadvantageous circumstances. Feeling off colour with a threatening cold, I took 15 grains of antipyrine and 5 grains of caffeine citrate in half a glass of hot water, and followed this by a good breakfast. I then went down to the Melbourne Dental Hospital and, sitting upright in the dental chair, had the following administrations given to me by Dr. Aird.

First Administration.

Pulse before induction (good, regular) ...	100
Blood pressure before induction	158 mm.
Anaesthetic—Ethyl chloride by the semi-open method	8 c.cm.
Pulse 1 minute after induction began ...	104
Blood pressure 1 minute after commencing induction	170 mm.
Pulse 2 minutes after commencing induction	102
Blood pressure 2 minutes after commencing induction	162 mm.
Time of induction	2 min. 10 sec.
Duration of anaesthesia	5½ min.

There was then an interval of fifteen minutes before the second administration—this time semi-open somnoform.

Second Administration.

Pulse before commencing administration ...	80
Blood pressure before commencing administration	158 mm.
Amount of somnoform used	5 c.cm.
Pulse 1 minute after administration ...	104
Blood pressure 1 minute after administration	176 mm.
Pulse 2 minutes after administration ...	104
Blood pressure 2 minutes after administration	164 mm.
Time taken to induce full anaesthesia ...	2 min. 35 sec.
Duration of anaesthesia	4½ min.

Interval of fifteen minutes. This time the method used was open ethyl chloride.

Third Administration.

Pulse before commencing administration ...	84
Blood pressure before induction commenced	156 mm.
Amount of ethyl chloride used	13 c.cm.
Time taken in inducing full anaesthesia ...	2½ min.
Pulse 1 minute after induction	102
Blood pressure 1 minute after induction ...	150 mm.
Pulse 2 minutes after induction	104
Blood pressure 2 minutes after induction ...	156 mm.
Duration of anaesthesia	5 min. 40 sec.

The first administration was commenced at 11.35 a.m., and the third at 12.20 p.m. Following upon the third administration I felt slightly sick, but with no real tendency to vomit. I left the hospital at 12.45 p.m., and after a pick-me-up enjoyed a hearty lunch at 1 p.m. It will be noticed that the blood pressure rose during induction in both the semi-open methods and remained about normal during the open method of induction. The pulse rate also rose during induction, and was always of good volume. On each occasion the anaesthetic was taken quietly, without any attempt to struggle, and in all three administrations the induction was of a quite pleasant nature. At no time was there the least feeling of want of air, fullness in the head, or pulsation of the heart, but just a very pleasant sensation of drifting off to sleep, with a creepy feeling gradually spreading from the feet upwards.

At the Melbourne Dental Hospital all general anaesthetics are given in the upright position at an angle of about 80 degrees. In my own work, for all classes of cases and patients of all ages, I always prefer the head and shoulders well raised and at an angle comfortable for the patient during induction. Whatever general anaesthetic is used comfort of the patient during induction is an essential. No patient can take an anaesthetic decently if he is in an uncomfortable position while going under. The same patient who will resist going under in a head low or prone position will take chloroform quite naturally and quietly if sitting comfortably in an armchair. He will have none of that feeling of fullness in the head or increased pumping action of the heart, so frequent and so very disturbing to a full-blooded patient when placed in the prone position. The comfort with which a patient will take a general anaesthetic in the upright position, as against the distress felt when in the prone position, was markedly illustrated in many cases in which I was able to give chloroform and ether to able-bodied men in the Royal Navy and Royal Australian Navy during the war. I was fortunate in having frequent opportunities of trying induction on one and the same patient in both the prone and the upright position, and the lurid remarks passed by these men against the prone position, as compared with the upright or semi-upright, were very instructive.

Persons undergoing general anaesthesia show during induction a marked tendency to cerebral congestion, which expresses itself as cerebral excitement and a tendency to struggle; this is especially the case if the patient is not comfortable. No anaesthetist should commence his work until he is assured of the comfort of his patient. With an upright patient not only is there less tendency to struggle, which means there is less strain thrown on the heart, but less anaesthetic is required for induction purposes. We are working with the advantage of a not overcongested brain. The anaesthetist can always lower the patient quietly to a more prone position for the comfort of the surgeon, after induction, should it be necessary to do so. Personally, I always prefer to retain, whenever possible and not inconvenient to the surgeon, a certain amount of head and shoulder elevation throughout the operation.

Conclusions.

Using these methods for over thirty years in patients of all classes and all ages, I have not had a single anaesthetic fatality. During induction we require a brain as anaemic as possible; we can get all the congestion required from the anaesthetic itself during induction. Induction of anaesthesia in a patient with a congested brain produces struggling, general discomfort, noises and a feeling of fullness in the head, and throws an extra strain on the heart. If that heart is abnormal or lacking in tone, then the extra strain may result in collapse and in a death, which might have been avoided.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

LEPROSY IN AN INFANT.

MANY cases of leprosy in infants have now been recorded, but in the present instance some unusual clinical details appear worthy of publication.

A female child was born in the leper home at Kangpokpi (Manipur State, Assam) on December 25th, 1924; both parents were Kabui Nagas undergoing treatment for leprosy. The mother was said to have had leprosy for twelve years, but the only signs of the disease were a few anaesthetic patches. The father had more extensive lesions and raised bacilli-bearing patches; after the birth of the child he developed a nodular eruption, thus proving that his disease was systemic and infectious.

The child at birth was noticed to have an ulcer on the plantar aspect of the right heel, about one-half by three-quarters of an inch; it did not readily heal on the application of zinc oxide ointment, and at the end of a week, since the child was born of leprous parents, it was thought wise to put her on local applications of hydnocarpus oil. Within two weeks the ulcer had healed completely, leaving a firm but slightly depressed scar, which has not broken down.

In May, 1925, the child and her parents were discharged as probably cured, but returned in seven months' time; before they left the colony no evidence of leprosy could be found in the child, but on its return a typically discoloured patch, measuring about 2½ by 3 in., on the left scapular region was noticed; this was treated by the usual method of subcutaneous injections of hydnocarpus oil and creosote (4 per cent.), and entirely cleared up in two months. There has been no recurrence since (June, 1928), and the area which was affected is normal both in colour and sensation.

Soon after the return to the asylum of the parents the mother of the child developed ascites, with a large liver and spleen; she went downhill rapidly and died greatly emaciated. No necropsy could be performed. The child is still living with the father.

The question at once arises whether this is an authentic case of pre-natal leprosy. If it is, then the theory that leprosy can be transmitted to the offspring of lepers before birth is strengthened. The initial ulcer, though suspicious, cannot be definitely proved to have been of leprous origin, and it is known that hydnocarpus oil will heal indolent ulcers when other remedies fail. *B. leprae* was not found in the ulcer, but this certainly does not exclude the diagnosis of leprosy, and anaesthesia in such a small child

was very hard to determine. The fact that signs of leprosy appeared in the child some months later strengthens the view that the initial lesion was of the same origin.

From whence did the child get the infection if it was pre-natal? The mother was not an infectious case, by the ordinary tests, and therefore it is questionable if she infected her child. Did the infection come through the father? Japanese workers have demonstrated that the testicle is one of the earliest infected organs, and Dr. Kobayashi uses the method of puncturing this organ as a means of diagnosis in doubtful cases which are sent to the Oshima Leper Home. Infection may therefore have been transmitted by the father, but it is strange that the heel should be affected first.

We consider that the case reported is unique, and that it is worth while recording it in the hope that others who have greater experience may be able to throw light on this question.

G. G. CROZIER, M.D.,
Superintendent, Kangpokpi Leper Home, Assam.

Medical Adviser, Mission to Lepers.

A CASE OF BILATERAL SYNDACTYLISM.

THE following case may be of interest as a surgical curiosity.

The patient, a young man of eighteen, has the middle and ring fingers of each hand joined together throughout the whole length of their normally contiguous surfaces. Each finger otherwise appears as a separate entity.

On both sides (1) the skin on the palmar aspect of the two fingers forms one plain surface, (2) the groove on the dorsum runs between the whole length of the fingers, (3) each nail is separate, and (4) there is free movement in all joints except the distal, the two fingers working together.

In the right hand, the distal joints are fixed in the position of extension, and the middle finger is longer than the ring, as is usual. In the left hand the distal joint of the middle finger is markedly hyper-extended, while that of the ring finger is apparently so to a less degree. This makes the two fingers appear of equal length.

From the radiogram it will be observed that the bones of each finger are normal, with the exception of the terminal phalanges, which are fused. In the right hand an exostosis has grown laterally from the tip of the ring finger to unite with the shaft

of the middle, and there are arthritic changes in the joints of both fingers. In the left hand, the proximal and distal ends of the phalanges are joined together, but the shafts of the bones are separate. This is evidently the cause of the hyper-extension of the middle finger, the joint of which is dislocated. The apparent hyper-extension of the ring finger is shown as really being a bowing backward of the phalanx. Here again the joint has undergone arthritic changes.

As regards family history, it is interesting to note that an uncle on the father's side had the same condition.

No treatment has been suggested, as there is very little disability, and any operative intervention would probably have no beneficial result. I understand that syndactylism of the fingers, particularly to the extent described, is not common, and have therefore ventured to record the case.

Kidderminster. C. PETVIN PORTER, M.B., Ch.B.

BABY BORN WITH A "TAIL."

THE following case seems to be of sufficient interest as a rarity to report.

On November 23rd, 1928, a Chinese woman gave birth to a full-term baby girl with a "tail" 1½ inches long. The baby weighed 6 lb. 9 oz., and appeared to be normal in all other respects. This was the third pregnancy, and there was no history of abnormalities in previous children.

On the fifth day the "tail" was removed by operation under local anaesthesia. It was not homologous with the tail of the lower animals, but was an outgrowth, consisting of skin and subcutaneous tissue only, from the region of the fourth sacral vertebra, the spinal column itself being complete. The baby left hospital on the sixteenth day in fairly good condition, though not yet having regained its birth weight.

I am indebted to Dr. F. R. Ashton for permission to publish this case.

Alice Memorial Hospitals, Hong-Kong.

Reports of Societies.

CHRONIC DYSPEPSIAS IN CHILDHOOD.

AT a meeting of the Medical Society of London, held on March 11th, with the president, Dr. J. W. CARR, in the chair, a discussion took place on the chronic dyspepsias of children over the age of infancy.

Dr. REGINALD MILLER said he proposed to deal with the subject partly by comparing chronic indigestion in children with that in adults and partly by considering certain points of more than ordinary difficulty. In regard to the former he thought that the chief difference in the child lay in the diminished importance, both in frequency and severity, of gastric as opposed to intestinal dyspepsia. From this it followed that local abdominal symptoms were far less marked in children than in adults, being often overshadowed by the general constitutional symptoms. Dr. Miller divided the dyspepsias of childhood into three etiological groups: gastric, hepatic, and intestinal. Dealing with gastric cases under the usual subdivisions of organic, reflex, and functional disorders, he pointed out the rarity of the organic group and the infrequency of the reflex group, with the exception of those cases where chronic appendicitis caused gastric symptoms. The subject was controversial, but he thought it fair to say that in the child pain in the right iliac fossa connoted disease of the appendix or neighbouring organs far more constantly than in the adult. Of the functional gastric dyspepsias less work had been done in investigating those of children than of adults, though one recent paper had suggested that hyperchlorhydria was a common cause of dyspepsia in children. In cases where a sharp pain was felt directly after food Dr. Miller believed that it was produced in the intestine rather than in the stomach, and was the result of stimulation of peristalsis. Weakly older children might have atonic dropped stomachs, and there was a rare group of cases of gastromegaly, the causation of which was not understood. Dealing next with the so-called hepatic cases, Dr. Miller stated that he thought many of the symptoms could really be traced to intestinal toxaemia with secondary disturbance of the liver. He said that, with regard to cyclical vomiting, there had been a tendency of late years to claim that a very large group of cases with chronic symptoms, not only nervous, but also abdominal, were due to a sort of latent acidosis with lowered alkalinity of the blood. It had been stated by Dr. Cameron[1] and Dr. Osman[2] that 30 per cent. of hospital children suffered from cyclical vomiting, but in view of the high bread and low fat diet of the hospital child Dr. Miller wondered whether the terms acidosis and cyclical vomiting were being used in their accepted sense

[1] *British Medical Journal*, February 2nd, 1929, p. 185.
[2] Ibid., January 26th, 1929, p. 159.

He thought that such latent acidosis would be relieved by comparatively small doses of alkali, and maintained that the correct sequence of events was, first, intestinal indigestion, then toxaemia arising from this, and, finally, as a result of the toxaemia, constitutional symptoms, including those of the nervous system. In diagnosing intestinal indigestion, the general symptoms of which were not always immediately suggestive of disorder of digestion, and might be attributed to psychological causes, he relied upon four signs. These were: enlargement of the abdomen, the occasional or persistent occurrence of obviously abnormal stools, the presence of gross indigestion as shown by microscopical and chemical examination of the faeces, and the presence of much indican in the urine. Certain types of intestinal indigestion could be recognized by careful examination of the faeces. These types included coeliac disease, shown by malabsorption of fat, starch indigestion, an uncommon form due to gross overfeeding with starch, paraffin indigestion, caused by overdosage with liquid paraffin, nut indigestion, possibly resulting from the use of the various preparations of bran and husks now on the market, cases associated with the presence of Lamblia, and cases of constipation with toxaemia. Why was one constipated child in perfect constitutional health and another obviously ill from toxaemia? The cause of the toxaemia was thought by some to be purely mechanical, while others invoked the presence of some abnormal bacterial infection. Dr. Miller said he had been unable to correlate toxaemia with any changes in the intestinal flora. Lastly, he referred to the frequency with which mucus was found in the stools of many patients with intestinal indigestion, a fact suggesting that the cause of toxaemia lay in a colitis which increased the permeability of the colonic wall.

Dr. W. G. WYLLIE stressed the close interplay in young children between the gastro-intestinal and the nervous systems. In many intestinal disorders nervous symptoms occurred which were no doubt secondary, although they often predominantly coloured the mother's picture of the child's ailment. In certain gastric disorders it was not so clear that the nervous symptoms were necessarily secondary, and, indeed, it often appeared that the reverse was the case. The liver undoubtedly played an important part in all the dyspepsias, but liver function tests had so far failed to indicate in what manner the liver was inadequate except in cyclical vomiting, where it was known that a glycogen depletion occurred. Another important feature of the dyspepsias in childhood was the abundant manufacture of mucus in the gastro-intestinal tract. Dr. Wyllie classified the chronic dyspepsias of childhood in two groups, roughly intestinal and gastric, but he emphasized that many of the terms used merely denoted clinical features and were lacking in scientific precision. Chronic intestinal dyspepsia he described as essentially a disease of the urban child of the hospital class. The symptom-complex included various "nervous" manifestations, such as restless nights, while fainting attacks and signs of vasomotor disturbance were also present. Sometimes wasting, loss of appetite, and a cough led to the suspicion of tuberculosis, and in some cases a troublesome papular rash was a marked feature. All these symptoms diverted attention from the bowel, but undigested food and excess of mucus in the stools were invariably present. A tendency to diarrhoea and great excess of mucus brought some of the cases into the category of "mucous disease." About the causation of coeliac disease, continued Dr. Wyllie, the two prevalent views were that it was due to a bacterial infection, possibly by organisms of the dysentery group, or, alternatively, to a primary disorder of fat metabolism. He mentioned recent work which showed that in cases of coeliac disease the blood fat was above normal. In chronic colitis it was very important to have the stools examined bacteriologically: in four recent cases Dr. Wyllie had found the Sonne type of dysentery bacillus. In cases of the gastric type vomiting was the prominent symptom. The speaker described first bilious attacks which occurred especially in children of a pronouncedly nervous disposition, and secondly, cyclical or recurrent vomiting. With regard to this latter disorder he thought further scientific proof was required to settle what were the exact disturbances of fat and carbohydrate metabolism present. These attacks of cyclical vomiting occurred in children of a peculiarly nervous temperament, often with a neurotic strain in their forebears, and it seemed to Dr. Wyllie that it was more reasonable to hold that cyclical vomiting was of directly cerebral origin than that it was dependent upon an intestinal disorder. In conclusion, he mentioned the relationship between dietetic deficiencies, including deficiencies of vitamins, and gastro-intestinal disorders.

Dr. B. E. SCHLESINGER said that while much clinical knowledge of the dyspepsias of childhood was available very little was known of their etiology. With regard to cyclical vomiting he inclined to the view that the cause was primarily nervous, and cited the case of a child with migraine, cyclical vomiting, and vasovagal attacks not unlike epilepsy, in which the fits were entirely brought to an end by a judicious diet containing increased carbohydrates and decreased fats. He knew a family in which one child had migraine and another cyclical vomiting, and suggested that both conditions might be related to some disturbance in the circulation of the brain. In this connexion it was of interest to note a case of migraine in a child who had also shown a persistent rise in blood pressure, quite uninfluenced by drugs, and another case in which vertigo and cyclical vomiting were associated; reduction of the blood pressure by means of liquor trinitrini had led to cessation of symptoms. He was interested in the class of "nut indigestion" mentioned by Dr. Miller, and he wondered if wholemeal bread might cause a similar disturbance. Dr. Schlesinger said that neither in the colitis of children nor of adults had he found alteration in the bacterial flora, and he suggested that the production of mucus in such cases, which was so little understood, might be a defensive mechanism on the part of the body.

Dr. F. G. CHANDLER inquired as to the origin of foul breath in dyspeptic cases. He also asked for help in the diagnosis of a patient, a sturdy boy of 6, who had frequent attacks of pallor with distension of the abdomen and urgent desire to defaecate after food. He also inquired as to the importance of air swallowing in the child, and whether food idiosyncrasies played any part in the dyspepsias of childhood.

Dr. W. S. C. COPEMAN, dealing with the problems of etiology, suggested that the trouble might begin in the infant, and that dyspepsia in later life might be due to dietetic and therapeutic errors in the infant. A study of infant feeding in France and Germany indicated that a much higher carbohydrate diet was favoured than in this country, and in the adult state the Frenchman was reported to be less liable to hyperchlorhydric dyspepsia than the natives of those countries where higher protein diets in infancy and childhood were employed. In certain cases of whooping-cough treatment with large doses of alkalis had led to a prolonged and persistent alteration in the hydrochloric acid content of the gastric juice.

The PRESIDENT said he had been struck by the references to the catarrhal condition of many children attending out-patient departments, and he had many years ago referred to the condition as a "muco-membranous catarrh" which affected both the respiratory and the gastro-intestinal tracts. He was of the opinion that measles played an important part in the production of the dyspepsias of childhood, and while the respiratory complications of measles were more widely recognized and were more serious in their results, the dyspepsias which arose after measles were numerically very noticeable. Children thus affected suffered for weeks and even for months from a dyspepsia in which loss of weight, loss of appetite, flatulence, and usually diarrhoea were prominent symptoms. He thought the prevalence of such cases after measles favoured the theory of a bacterial origin for many of the dyspepsias of childhood.

Mr. ZACHARY COPE said that he thought several surgical conditions which gave rise to dyspeptic symptoms should be mentioned. He instanced chronic tuberculous glands in the abdomen, whether calcified or not, which often gave rise to colicky pains which might be very vague and puzzling in their nature. Unless the condition was diagnosed early an acute intestinal obstruction might arise demanding a dangerous operation. Chronic intussusception might also give rise to a dyspepsia lasting for weeks, and

the tumour was not always felt in such cases. Finally, tuberculous peritonitis might cause dyspeptic symptoms associated with some distension of the abdomen.

Dr. MILLER said, in reply, that measles was so commonly the first and most debilitating infectious fever from which children suffered that it was bound to precede many cases of dyspepsia without having a causal connexion. He thought it dangerous to speak of the surgical conditions enumerated as dyspepsias. In reply to several questions he said that air swallowing was very common in children, and that while the cause of foul breath was often unknown, he had seen cases in which not only the breath but the whole patient had a disagreeable odour. He agreed with Dr. Wyllie as to the primary cerebral origin of what was generally accepted as true cyclical vomiting. With regard to coeliac disease, he thought it was also a question of careful definition, and he set out his reasons for being unable to accept the theory that this condition had a bacterial origin.

Dr. WYLLIE, replying briefly, stressed the importance of increased knowledge of the chemistry of the intestinal canal in cases of dyspepsia in childhood. He thought a low-grade infection might alter the chemistry of the cells of the intestine without actually producing obvious lesions.

DIAGNOSIS AND TREATMENT OF LOW BACK PAIN.

AT a meeting of the Orthopaedic Section of the Royal Society of Medicine, on March 5th, Dr. M. D. SMITH-PETERSEN (Boston, U.S.A.) opened a discussion on low back pain by considering the differential diagnosis between lumbo-sacral and sacro-iliac conditions, and reviewing the operation of sacro-iliac arthrodesis and its end-results. The president, Mr. NAUGHTON DUNN, was in the chair.

Dr. Smith-Petersen said that the differential diagnosis between lumbo-sacral and sacro-iliac conditions was not dependent upon any one pathognomonic sign; it could only be made on the basis of a careful history, covering an analysis of injury and its resultant pain distribution. By such a carefully taken history ideas were formed in regard to the diagnosis, so that the examination itself became more productive of evidence differentiating the two regions. In a general way it might be said in relation to injuries that leverage applied from above and producing hyperflexion of the spine resulted in muscle or ligamentous sprain, or, if very severe, compression fractures. Lifting injuries, on the other hand, might cause muscle sprain of the erector spinae, or ligamentous sprain of the sacro-iliac joints. The pain resulting from such an injury was necessarily dependent on the innervation of the structures involved. Injury of the supporting ligaments of the spine brought about local pain at the site of the injury, sometimes accompanied by referred pain along the peripheral distribution or the particular spine nerve supplying the innervation. Sacro-iliac sprain was accompanied by local pain over the sprained ligaments, with referred pain over the peripheral distribution of the first and second sacral nerves, these nerves supplying the innervation to the sacro-iliac regions. This distribution of pain was commonly referred to as "sciatica," the area involved being the gluteal region, the posterior and postero-lateral regions of the thigh, the knee, calf, and outer aspect of the ankle. This term, "sciatica," was misleading, since it implied involvement of the entire sciatic nerve, whereas actually there was involvement only of the first and second sacral nerves.

Physical Examination.

In the examination the attempt must be made to be as systematic as possible; the examination should include inspection, palpation, and motions. Inspection did not yield any particular information which assisted in differential diagnosis; it was helpful only in determining the acuteness of the symptoms by observing the presence or absence of muscle spasm. Palpation was of great importance, and should be performed in such a way that the examiner at all times knew which anatomical structure he was palpating. It was decidedly useful in differentiating a lumbar from a sacro-iliac lesion, since lesions of these regions gave rise to a very definite localized tenderness over the particular structures involved, and these areas of tenderness did not in any way overlap. In examining the mobility of the spine this part of the examination should be carried out in standing, sitting, and lying positions, with particular reference to mechanical leverage of muscles in these positions. For example, forward bending was limited in the standing and sitting positions in lumbar lesions, whereas the same motion was limited in sacro-iliac lesions with the patient standing, but free with the patient sitting. In the lying position the same motions were induced but in a passive manner, and if gently performed would yield valuable information.

After such a careful history and examination, the next step, necessarily, was to submit the patient to x-ray investigation. It was not possible to make a diagnosis of sacro-iliac relaxation or sprain by an x-ray examination, since though the appearances might be confirmatory they were not diagnostic. The diagnosis must be based on clinical findings, and the x-ray examination should be resorted to purely for confirmation; in sacro-iliac relaxation it was frequently negative. If there was a long history extending over a period of years the changes that might be found were narrowing of the joint line, increased density along the joint, and hypertrophic changes along the inferior margin of the joint. Disalignment of the pubis as seen in stereoscopic x-ray examination was sometimes considered evidence in favour of a slight sacro-iliac disalignment, but it was not proof of such a condition.

Dr. Smith-Petersen said that it had been his experience that cartilage removed from the sacro-iliac joint in cases of recurring sprain or relaxation showed perfectly definite histological changes; it was only natural that these changes should be present. In sacro-iliac disalignment or sprain the congruous surfaces of the sacrum and ilium no longer fitted. Prominence came into apposition to prominence, and consequently the covering cartilage was exposed to abnormal pressure. Cartilage exposed to abnormal pressure underwent degenerative changes as follows. (1) Myxomatous degeneration of the matrix; this was shown by deeper staining reaction and by nesting of the cartilage cells. (2) Surface fibrosis; instead of the hyaline cartilage extending to the joint surface the surface of the cartilage was covered by a layer of fibrous tissue—evidence that nature was trying to repair the damage brought about by the abnormal pressure to which the cartilage had been exposed. (3) Degeneration of the matrix was followed by a replacement fibrosis, so that instead of there being a clear staining matrix there were connective tissue fibres winding in and out among the cells. Such replacement fibrosis was normally seen in older people between the ages, perhaps, of 60 and 70, but when it was found in persons aged 20 to 30 it was distinctly abnormal. (4) Calcification of the cartilage cells was one of the late changes; it was seen chiefly in the basilar region of the cartilage next to the osteo-chondral junction. The changes just described were, in the speaker's opinion, characteristic of a traumatic arthritis as it affected hyaline cartilage.

The Operative Treatment.

Dr. Smith-Petersen said that he had described the operative fusion of the sacro-iliac joint in detail in previous publications; an important change had been made since the last of these, and consisted in a resection of the posterior iliac crest, allowing better approximation of the periosteum and gluteal fascia to the lumbar fascia. This was important, since the region of operation was one exposed to constant strain. Great care must be taken to avoid stretching of the scar of the incision.

Post-operative treatment involved four weeks in bed. No plaster cast was applied, but only a surgical dressing held in place by means of a binder. The amount of pain during the first few days after the operation varied in different individuals. Some patients insisted that they had no pain as compared with the pre-operative condition, their relief being almost instantaneous. Other patients had relatively severe pain, an aggravation of the pre-operative pain; this might last for two, three, or four days. At the end of this period most patients were absolutely comfortable, able to move in bed, and even to rest on the side of the operation. They were allowed to lie in any

position in which they were comfortable. At the end of the third week the patient was gradually allowed to sit up in bed. At first the headpiece of the bed was raised to an angle of 30 degrees, and as the days went by this angle was increased. The patient was never allowed to sit up in bed without first having the footpiece of the bed raised so as to keep his knees and hips flexed. If a hospital bed was not available a large pillow was used for this purpose. At the end of the fourth week the patient got out of bed and began to stand up and walk. It almost invariably required another week before the patient was able to do a great deal of walking. At the end of the fifth week the patient left the hospital. Activities were gradually increased, but no exercises were prescribed until the end of the eighth week. At that time mild postural exercises were started, these being of such a character as not to put any strain on the incision or joint. Some patients had returned to relatively hard work at the end of two to three months; this had always been against advice. As a rule the speaker did not like patients to return to heavy lifting and labour until the end of the third to fourth month. At the end of six months the patient should be able to lead a normal life without restrictions.

End-Results.

Altogether 160 to 170 cases had been dealt with; of these they had recorded end-results in 100. No cases were reported which had been operated upon less than a year ago; this eliminated a certain number. In the remaining cases they had been unable to get into touch with the patients, either by mail or by actual examination, so that a true end-result could not be given. Of the 100 cases, 88 were absolutely successful, 8 partially successful, and 4 cases were considered to be failures. In the 8 partially successful cases the patients had returned to their former activities, but had occasional discomfort either in relation to their scar or discomfort in the region of the peripheral distribution of the first and second sacral nerves. They had been definitely improved by the operation, and were glad they had had it, but they were not complete cures. Of the 4 failures, 2 turned out to be cases of arthritis. The speaker believed that in arthritis the response to the operation was poor, and relief from pain was very slow in coming about; he therefore advised against an operation until every step had been taken to rule out a possible arthritic condition. Of the other 2 failures one patient went to another clinic for relief of low backache; a very radical bone graft operation was performed which resulted in persistent pain. In the other case also there was persisting lumbo-sacral backache; first and second sacral nerve pain had been relieved in all four cases, but the patients had been unable to return to their former occupation, and consequently should be classified as failures.

Successful cases constituted a group in which entire relief from pain had been secured. The patients had returned to their pre-injury activities, whether the patient was a society woman or a labourer. They were in no way limited, and this point the speaker emphasized: there was permanent relief from pain, resulting in unlimited activity. Anybody could treat these cases by recumbency, rest, support, manipulation, and even plaster casts, and temporarily achieve relief, but in the cases operated upon permanent relief had been achieved without limitations in activities. No case had been operated upon without first having been given a chance of relief by conservative measures such as those mentioned. The series of operative cases constituted, then, a small proportion of cases actually seen, the remainder being relieved by conservative measures. In a series of 400 industrial accident cases the diagnosis of sacro-iliac relaxation or sprain was made in 20 per cent.: the diagnosis was discussed in full and written down in the report. Of this 20 per cent. a small portion—less than 5 per cent.—had been operated upon. It was true, then, that the operation had never been employed without first thoroughly studying each case, and trying every normal method of conservative treatment.

SIR ROBERT JONES spoke of the treatment of such cases in his own early days in practice, forty-five years ago. His uncle had a very large industrial practice, and injury to the back, due to lifting weights or to falls, was very frequent among the cases he was called upon to treat. On examination a good many of the cases were found to be accompanied by sciatica and by pains, particularly around the glutei. The simple treatment consisted first of all of applying a little counter-irritant for the lower part of the back, and then the use of a paper-plaster, consisting of pitch put on thick plaster, six or eight layers of which made a very firm cardboard indeed. As a rule, after from three to six weeks, the patients got quite well, but a certain number did not, and in those days these were almost taken for granted to be neurotics, or perhaps malingerers. His own attention was drawn to the value of manipulation through his observation of a patient who, as the result of a fall, quickly recovered from an obstinate condition for which he had been under treatment more or less for two years. Thereafter the speaker manipulated the spine in these cases, often with astonishingly effective results. He learned a good deal as to the probable cause of the pain from Goldthwaite, the American orthopaedist, but he feared that frequent successes in the manipulative treatment of these back cases had induced a complacency which should never exist in surgery, and now Dr. Smith-Petersen had come along and proved conclusively that there was a type of case where it was not enough simply to say that there were adhesions which wanted breaking down, but that there was a distinct pathological lesion. He still thought, however, that in a great many cases recovery was obtained by the breaking down of adhesions; this was difficult to prove, but he felt that the same thing happened at the lumbar-sacral angle as happened undoubtedly higher up in the spine. It had never seemed to him that any pain had quite the same intensity as the pain of adhesions. In many cases in which the sacro-iliac joint and the lumbar spine were involved there was distinct inflammation and movement of structures with very little pain indeed. In early cases of tuberculosis, for example, there was not very much pain, and even in advanced tuberculosis, with a very mobile joint, the pain was often the least prominent of the symptoms. An American orthopaedic surgeon sought his advice in a case of sacro-iliac trouble which had lasted for a long time and resisted all forms of treatment. The speaker urged that an attempt be made to break down any adhesions, and somewhat sceptically the attempt was made, with the result that the case yielded readily to manipulation. While he agreed with everything that Dr. Smith-Petersen had said, he would still, in a typical case, before venturing to operate, try to break down adhesions, a course of action which often produced quite dramatic effects.

Dr. STACEY WILSON (Birmingham) emphasized that any injury of the spine was certain to be followed by a muscular contraction to protect the injured part, and that after recovery from the injury the habit of contraction would remain. This spasmodic contraction, which was the cause of the continuance of the trouble, could be overcome by rhythmical exercises, of which the speaker gave a demonstration.

Mr. A. S. B. BANKART thought there was no doubt as to the existence of adhesions which needed to be broken down. He noted the omission from Dr. Smith-Petersen's lecture of any mention of the commonest cause of backache—namely, the neurotic spine; not the "hysterical spine" of young girls, but a definite neurosis superimposed upon a lesion. This coloured the whole symptomatology of these simple conditions. It accounted for the diversity of symptoms which had been described, and opened a wide and profitable field for every conceivable kind of therapeutics.

The PRESIDENT said that his experience was that most of the cases got better by conservative treatment, but the results from operation which Dr. Smith-Petersen had shown were certainly astounding.

Dr. SMITH-PETERSEN said that he was accustomed to use manipulations, which he had included under the term "conservative methods." His conservative treatment consisted of supports, but if there was any evidence of disalignment he used manipulations. At the same time, American orthopaedic surgeons did not appear to have been so successful in regard to manipulations as their British colleagues.

DOSAGE IN RADIUM THERAPY.

A MEETING of the Section of Surgery of the Royal Society of Medicine was held, under the presidency of Sir HOLBURT WARING, on March 6th, at the Middlesex Hospital, when Professor SIDNEY RUSS gave an address on some principles of dosage in radium therapy. A demonstration of cases treated with radium by the surgeons of the Middlesex Hospital took place at the end of the meeting.

Professor Russ advanced some considerations on the amount of screening desirable in the application of radium. If it was desired to carry out pure gamma-ray therapy a screen was required which would cut out all the alpha and beta radiation. To cut out the alpha radiation was easy, but it was difficult to say what thickness of screen sufficed for the beta. Physicists appeared to be agreed, however, that 1 mm. of platinum or 2 mm. of lead and silver would give over 99 per cent. of what they called easily absorbed radiation. There had been some controversy as to whether better results were obtained with 1 mm. of platinum or with 1.5 mm., but so far as his own investigations had gone he had not been able to discover that the additional screening furnished essentially different results. From a survey of physical considerations he thought it could be said that a pure gamma radiation was being dealt with when a screen of 1 mm. of platinum was employed. The main principles of dosage were: (1) to produce a lethal action on malignant cells; (2) to do as little damage as possible to normal tissues; (3) to encourage local reactions in normal tissues which would assist the disappearance of the tumour; and (4) to secure as uniform a radiation of the malignant mass as possible. Animal experiments had shown the lethal action from a radium tube to be rather surprisingly limited to a zone around the tumour. Generally speaking, it would be correct to say that radium must be looked upon as supplying a localized form of treatment. A very important matter in radium dosage was to avoid damage to the normal tissues. This had been for years recognized by the French school, who gave the name of "radio-necrosis" to the actual destruction of normal tissues which might accompany the irradiation of a tumour. Dominici and others had laid great stress on the ill effects of giving an overdose to the normal tissues. Not only did this hinder the gradual transformation of the malignant cells, but it interfered with any processes which the body—the host—might put forward in the endeavour to complete what radiation had begun. An essential point was to encourage any local reaction of which the body was capable. It was also very desirable so to arrange the radiation that the malignant mass was as uniformly irradiated as possible, save perhaps for additional irradiation at the growing edge, where the normal tissues of the host were being invaded. Professor Russ showed photographs of radium tubes variously disposed, with a view to pointing out that, if some regions received an adequate irradiation, other regions must receive an irradiation which was less than adequate. The time-intensity element raised one of the most important considerations in radium dosage. Here the biological reaction differed from and was less predictable than the physical. If it was a question of ionizing the air or affecting the photographic plate, then big intensity for a short time and small intensity for a long time were equivalent over a wide range. In the case of the biological reaction other factors appeared to intervene. Some remarkable results had been obtained in radium therapy by using the radium for longer intervals and cutting down the intensity of the radiation. One reason put forward to explain the increased effect was that the cells in a growing mass of tissue, being in a state of division, would be more vulnerable to the long-continued application. Professor Russ, however, was doubtful on physical grounds whether this reason was correct, and he said also that it was not agreed among clinicians that all growths were better treated with small doses for longer time. In the Stockholm technique for the treatment of cancer of the cervix uteri a strong dose for a short time was employed. In conclusion, he suggested that it might be worth while to consider whether the normal tissues generally, while able to cope perfectly well with a certain intensity of radiation, might not be overwhelmed when that intensity was exceeded. One could apply a source of radium to a subcutaneous nodule in such a way that a slight damage to the skin was caused, but with a more limited intensity, while the nodule equally disappeared, there was no skin damage. The action so far as the nodule was concerned was apparently the same, but in respect to the skin it was different. Was it that, when a certain intensity was exceeded, the processes in the normal tissues which would repeatedly restore equilibrium were no longer able to function?

Dr. EDGAR HAYDON (Newton Abbot) related some experiences of radium treatment in a small hospital in South Devon. Large doses of radium in uterine cases had proved most successful. In cases of antrum trouble he had also seen better results from fairly large doses of from 50 to 100 mg. A small incision was made in the cheek, piercing the wall of the antrum, and 100 mg. was left in for about eighteen hours or 50 mg. for thirty hours. He described also how the tongue and tonsils had been treated by the implantation of radium tubes. For surface radiation the method had been followed of encircling the growth, keeping the tubes a distance of 1.5 cm. apart, and pointing them to the centre of the growth.

Dr. MALCOLM DONALDSON said that clinically this question of dosage continued for a long time was very important. He was not altogether convinced that even in such cases as carcinoma of the cervix the heavy intensity for the short time was the better course. He would put it rather in this way, that in certain growths it was not so essential to have length of time. Professor Heyman of Stockholm had declared recently that 50 per cent. of his recurrences occurred *in situ*. This never happened when doses were applied of small intensity for a long time. The actual condition *in situ* was better in the case of growths treated by a small dose for a long time.

Sir HOLBURT WARING described a case in a girl, aged 14, who had been treated by radium two years previously for what was supposed to be sarcoma of the maxilla. She responded to treatment in that there was no evidence of local recurrence; but she had recently again come under observation on account of acute intestinal obstruction with general peritonitis. She was operated upon, and in a segment of the small intestine was found what was apparently a tumour mass. On excision and microscopical examination it was pronounced by the pathologist to be a sarcoma of the intestine, in his opinion secondary to the growth which had been cured in the jaw. He would have liked to hear opinions with regard to local and secondary recurrences in connexion with the problem of dosage. It seemed a matter in which a good deal of co-operation was called for between surgeon, radiologist, biochemist, and biophysicist.

HYSTEROTOMY AND TRACHELOTOMY.

AT a meeting of the North of England Obstetrical and Gynaecological Society on February 22nd, with the president, Dr. G. W. FITZGERALD (Manchester), in the chair, Dr. J. W. A. HUNTER (Manchester) read a note on hysterotomy.

Dr. Hunter pointed out that the word "hysterotomy" was used both for an incision into the uterine body through an abdominal incision and for an incision of the cervix per vaginam. He suggested that the word "trachelotomy" was more suitable for the latter operation, and he used it throughout in his note. Trachelotomy could be employed to facilitate the emptying of the gravid uterus either during pregnancy or at full term, when it was usually performed during labour. The note dealt with the use of the operation in labour; the cases of failure of the cervix to dilate were divided into two classes: (1) those in which the cervix was normal, and (2) those in which the cervix was abnormal either in size or consistency. The mechanism of normal cervical dilatation was described, and failure of this was noted as frequently due to premature rupture of the membranes, associated with slight disproportion between the foetal head and the maternal pelvis. The lecturer cited cases where the cervix was abnormal in length or structure; these were the cases where the cervix was congenitally long or elongated as a part of prolapse,

and those in which it was hard, thick, and fibrous, but not appreciably elongated. The last type was seen in elderly primigravidae, or in multigravidae as the result of scar tissue formation. The cases might be complicated by premature rupture of the membranes, slight extension of the head, or occipito-posterior positions. The patients were usually left for a considerable time, to give the cervix a chance of dilating, but eventually their pulse and temperature began to rise. There was often a history of considerable intervention, and the child might be dead. Recognized methods of delivery had difficulties and disadvantages. Trachelotomy allowed clean incisions into the cervix, which could be stitched up carefully immediately afterwards; it permitted delivery by forceps or craniotomy. The methods described involved one or two postero-lateral incisions from the external to the internal os, behind the middle line to avoid the cervical branches of the uterine artery. This length of incision prevented it extending further during delivery. If two incisions were decided upon it was important to mark the site of the second before making the first, since, after the first, much retraction occurred and orientation was difficult. The importance of accuracy of apposition in suture of the incisions was emphasized.

Clinical Demonstrations.

Professor CARLTON OLDFIELD (Leeds) showed a specimen of some foetal bones and a uterus removed after death. The foetal bones had caused intestinal obstruction.

The patient had had a Caesarean section performed in March, 1926. In July, 1927, she was admitted to hospital with abdominal pain; she was found to be six months pregnant, and had been taking "salts" to produce abortion. She had similar symptoms in December, 1927, with a little vaginal discharge, but left hospital well early in January, 1928, and was told to report just before full term. She was readmitted acutely ill in April, 1928, and said she had miscarried shortly after her discharge in January. She now had an inflamed swelling at the upper end of the old abdominal scar which, a day or two later, discharged pus and faeces. This was opened and two fistulae into the intestine were repaired, but she died of intestinal obstruction. At the necropsy a rupture was found in the old uterine scar, and the foetal bones were found in an enlarged loop of the small intestine just below the loops in which the fistulae had been repaired.

Mr. N. L. EDWARDS (Derby) described a case of uterine fistula following Caesarean section.

The patient, aged 25, had had a Caesarean section performed for obstructed labour in 1923; the convalescence from this was uneventful, no rise of temperature being recorded. A year later the upper end of the wound broke down, discharging a small quantity of pus. The sinus persisted and after May, 1928, menstrual fluid escaped from it at the menstrual periods, which were regular. In September, 1928, the fistulous track was excised entire, together with a wedge of the anterior uterine wall in which were embedded two thick silk sutures. Sections of the fistulous track showed no evidence of endometrioma. The case illustrated the dangers of unabsorbable sutures in the uterine wall.

Considerable discussion followed, several members expressing the opinion that it was the method of suture rather than the material used which mattered in ensuring a well-healed uterine scar.

Professor CARLTON OLDFIELD recounted two cases of ruptured malignant ovarian cysts admitted as acute abdominal emergencies.

In each case when the abdomen was opened it was found full of "boiled sago" like material, which was mopped out and the ruptured cyst removed; both abdomens were reopened later and the rest of the generative organs were removed. Both patients had had prophylactic deep x-ray treatment since the operation. One patient had remained well for three and a half years, when she developed symptoms suggesting a recurrence. The other patient had a recurrence a year later in the transverse colon; fifteen months subsequently there was one in the jejunum, and now, another fifteen months later, one had appeared in the roof of the vagina involving the bladder.

Discussion was particularly invited on the use of prophylactic deep x-ray treatment, and on prognosis in malignant ovarian neoplasms. Several members expressed the opinion that deep x rays were not without danger, and that the prognosis in these cases was not so bad as was usually thought.

Professor FLETCHER SHAW (Manchester) read notes on a case of uterine diverticulum in a patient, aged 34, who had been married for eight years and was sterile.

She complained of recurrent severe pain in the left iliac fossa at the menstrual period. Examination revealed a mass the size of a small orange in the region of the left appendage. At an operation this mass was found to be a cystic left ovary. In the left broad ligament there was a hard tumour of regular outline, about 1½ inches long and 1 inch wide; its upper border was about half an inch below the round ligament and Fallopian tube, and in no way connected with either. It was enucleated from the broad ligament by a considerable amount of blunt dissection; the pole nearest to the uterus had to be cut out with scissors. Sections showed that the tumour had a thick outer muscular coat, and contained a cavity lined with endometrium, but with no retained blood. Its relation to and its entire separation from the round ligament and Fallopian tube precluded it from being described as a poorly developed uterine horn. Professor Fletcher Shaw considered it to be a diverticulum budded out from the uterine cavity, and then shut off therefrom.

Miss IVENS (Liverpool) recorded a case of puerperal gas gangrene infection.

A primigravida, aged 28, had had no ante-natal care, and came into labour one month after the expected date. Many vaginal examinations had been made and a forceps delivery attempted before she was admitted to hospital. On admission the maternal pulse was 128, the temperature 98° F., and the child was dead. There was a putrid offensive vaginal discharge; the cervix was three-quarters dilated and lacerated. Perforation and cleidotomy were necessary to effect delivery. The cervix and perineum were repaired; an intrauterine douche and an injection of antistreptococcal serum were given. The next day she received 20 c.cm. of the Weinberg antigangrene serum, and 20 c.cm. anticoli serum subcutaneously with saline solution. *B. aerogenes capsulatus* was recovered from the lochia by inoculation of a rabbit. The patient made an almost complete recovery, although the uterus remained high and fixed. Miss Ivens considered that when a woman after labour or abortion showed a yellowish tint and reddish urine it was probable that she was suffering from a severe gas gangrene infection. She recommended animal injection to identify the organism, and the early use of a powerful antitoxin.

OPPORTUNITIES FOR MEDICAL WOMEN ABROAD.

AT a meeting of the London Association of the Medical Women's Federation, held at the British Medical Association House on February 26th, with the president, Dr. HUXLEY, in the chair, the subject under discussion was "Opportunities for work for medical women abroad." Papers were read by Dr. M. E. JOHNSTONE (Canada) and Dr. K. ATKINSON (America), and letters on the subject were sent by Dr. Emslie Hutton (Near East) and Dr. M. Hickley (South Africa). Miss L. MARTINDALE and Dr. K. WARREN (Uganda) also contributed to the discussion. Dr. Johnstone spoke especially of the Province of Alberta, where she had been working under the Department of Public Health. There the opportunities were very good, as there was complete reciprocity in the matter of registrable qualifications; and, indeed, the Department of Public Health was now advertising for several women district medical officers to go out at once. The work was mainly among the women settlers. The infant and maternal mortality rate was at present excessively high, owing to the lack of medical facilities. The climate was one of extremes, but very healthy, and the whole province was in a state of rapid expansion and increasing prosperity. The prospects for Government medical work, or for general gynaecological practice in one of the larger towns, were very good at the present time, and would probably improve still more. Dr. Atkinson spoke of hospital work in the United States, especially (where her experience was greatest) in Philadelphia and San Francisco. After touching on the differences between the British and American hospital systems, she spoke hopefully of the prospects of gaining "intern" posts, and of the value of these, and the possibility of passing to resident appointments from them. Conditions on the whole did not appear to be vastly different from those prevailing in England. Dr. Emslie Hutton's letter was not encouraging for English women. Over the whole of the Balkan States and Russia there seemed to be practically no opening for their services, though for native qualified women there were numerous appointments. A few mission hospital appointments only were open to foreigners, but there was great opposition from officials. Dr. Hickley wrote of South Africa from two distinct points of view—namely, practice in large towns and "up country." The former was hopeful, as specialists were rare, and there was always scope for the running of a specialty in connexion with a general practice. She noted, however, that the supply of South African graduates was really sufficient for the needs of the country. Practice in the outlying districts she considered unsuitable for a woman, both on account of the difficulty of transport and the great distances that had to be traversed, and on account of the attitude of the natives. Mrs. Warren spoke of her work in Uganda, and implied that there was room for more women, but that up to the present the prospect had not seemed alluring, and practically none had applied. Government work was essential, as private practice did not yet exist. The British population was relatively very small.

Reviews.

SURGICAL PATHOLOGY.

THE textbook on *Surgical Pathology*[1] by Mr. CECIL WAKELEY and Mr. ST. J. D. BUXTON will probably attract particular attention, because works on that subject, although indispensable alike to students and practitioners, are comparatively scarce as compared with books on general pathology; of the latter there would appear to be almost a superfluity on the market. Practising surgeons, engaged in hospital work and teaching, and interested it may be in some special branch of surgery or in points of research arising out of their own cases, have little inclination to divert their interest into the work of a general survey; and probably few, other than born teachers, care to face the labour involved in so wide a field. In these days, therefore, a good book on surgical pathology is a thing to be prized. What a student expects to find in a work of the kind is a description which will help him to recognize any and every pathological condition or process that he is likely to meet with clinically, together with an account of its cause and possible consequences; and further, any points, although possibly of minor theoretical interest, which have a special bearing on surgical practice. To present these matters as simply and directly as possible, and in an attractive manner, is the aim which the authors have had in view, and as a practical, useful, and comprehensive guide to the subject, whether for students or practitioners, their book could not be bettered. Special care has obviously been taken with the index which is commendably full and clear.

In their preface, the authors, very properly, make no mention of examinations, but it would be unreasonable to suppose that even the serious student should take so disinterested a view of the subject as not to have the fear of the examination table before his eyes. He will naturally inquire how far the book is going to help him when confronted with a specimen which he has never seen before and which the examiner has studied beforehand. In order to acquit himself with comfort in these unequal conditions he will be wise to adopt the advice which the authors offer—namely, that if he uses their book he should do so in the museum and study it and the specimens together. Surgical pathology, they point out, cannot be learnt by means of mere verbal descriptions even with the aid of the best of illustrations; and as regards many surgical affections, those of the bones, for example, there is no place, other than the museum, where the subject can be properly and adequately studied. Students in this country are fortunate in having free access to the best museums in the world, and, if they adopt the advice given, they will find what is generally considered the laborious task of "going through the museum" much lightened and enhanced in interest.

The authors' manner of writing has a freshness and directness which certainly aids in maintaining interest; lengthy and verbose discussions on intricate pathological problems are avoided, and attention is concentrated on matters of immediate practical import. A word may be said with regard to the illustrations. It is notorious that, since the employment of photography in the illustration of medical works, constant use is made of figures which fail to show anything they are intended to show. This common blot on medical works has been scrupulously avoided by the authors; their illustrations are uniformly good and instructive, and it is to be hoped that the example thus set will be followed by others. The whole plan and execution of the work is good, and as the authors' position is a guarantee that the information contained in it is authoritative, there is every reason to think that the book will be used and appreciated. Students have long felt the need of a work of this kind, and it exactly meets the need.

AN INDEX OF SYMPTOMATOLOGY.

MESSRS. JOHN WRIGHT AND SONS of Bristol have recently issued *An Index of Symptomatology*[2] as a companion volume to their well-known series dealing with diagnosis, treatment, and prognosis. It is edited by Dr. H. LETHEBY TIDY in collaboration with twenty-five special contributors. The work aims at presenting for each disease a description of its clinical manifestations that will enable the practitioner to recognize a typical case, and the student to retain in his mind a picture of the condition in its most characteristic form. In general, this "index" follows the scheme of its companions, and, used in conjunction with them, it should help considerably in the solution of difficult diagnostic problems. The articles, which cover all branches of medicine, surgery, gynaecology, and the specialties, are tersely written and well up to date.

The book is illustrated with four beautiful coloured plates and a number of reproductions of photographs and charts. The radiograms are clear and convincing, though those depicting diseases of bone are, on the whole, more effective than the rest. The figures illustrating diseases of the skin are, however, not so instructive. It is doubtful if the appearance of even so characteristic an eruption as that of herpes zoster can be faithfully conveyed by a photograph in monotone. One realizes, of course, that the cost of production precludes the generous use of coloured plates, but in the illustration of skin conditions the expense of reproducing photographs hardly appears to be justified by their utility.

Dr. Tidy and his collaborators are to be congratulated on producing a volume worthy of the series to which it belongs.

MATERNITY AND CHILD WELFARE.

IN the preface to *Maternity and Child Welfare*[3] Dr. ETHEL CASSIE states that this work is primarily intended as a textbook for public health workers. During the last twenty-five years a new profession for women (that of health visitor), now numbering some thousands of trained workers, has come into existence. The Ministry of Health has gradually tightened up the qualifications till the necessary training has become a long and arduous one. A suitable textbook has been long overdue, and Dr. Cassie is to be congratulated on having, very largely, supplied the need. Most of the book is excellent; lucid, and easy to read, its teaching is simple and direct. Chapters on such subjects as health visiting as a profession, child welfare centres, ante-natal care, heliotherapy, and the minor ailments likely to be met with at school and special clinics, give just the facts which the public health nurse ought to know—facts which, hitherto, she has been unable to obtain except from scattered writings, or from lectures specially arranged for her benefit.

The section on breast-feeding might well have been extended. Little or nothing is said about such difficult problems as those of the nervous child (a condition which Cameron says is the cause of 50 to 60 per cent. of the failures [illegible] of the early and obstinate indigestion [illegible], or of the management of the crucial period when the mother is resuming her domestic duties; and wet-nursing is hardly mentioned. On these matters health visitors can hardly have too much information. Dr. Cassie's teaching as to the time taken in emptying the stomach, and its bearing on the right spacing of feeds, is curiously indecisive. Though advising three- or four-hourly feeds, she says there is very little left in the stomach at the end of two hours, and that regularity of feeding is more important than actual spacing; the reasons given for longer intervals being the trouble in preparing the feeds, the disturbance of the child's sleep, and the peristalsis induced by too frequent feeds. Health visitors might well have been provided with a stronger armoury

[2] *An Index of Symptomatology.* By various writers. Edited by H. Letheby Tidy, M.D.Oxon., F.R.C.P.Lond. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1928. (Sup. roy. 8vo, pp. xii + 710; 130 figures, 4 plates. £2 2s. net.)

[3] *Maternity and Child Welfare.* By Ethel Cassie, M.D., B.S., D.P.H.Ed. London: H. K. Lewis and Co., Ltd. 1929. (Demy 8vo, pp. viii + 228; 13 figures. 8s. 6d. net.)

than this for their difficult compaign against the traditional two-hourly feed. Leven, Barrett, and Ladd have shown that even in healthy breast-fed babies a considerable residue often remains in the stomach long after the expiration of two hours; and it is certain that indigestion, brought about by two-hourly feeds, is a frequent cause of inefficient suction and premature weaning. In the section on milk mixtures some of the quantities are obviously incorrect, which must tend to confuse non-medical readers. Cod-liver oil is recommended instead of additional cream or butter in the feeds (as much as 9 or 10 drachms in twenty-four hours for a baby weighing 14 lb.). In a textbook intended for non-medical women is it quite wise to advise such mixtures for continued use, especially in view of the warnings of Mellanby, and, more recently, of Agdur, as to the toxic effects of the oil in large or long-continued doses? Dr. Cassie speaks of additional feeds after a breast feed as "supplemental"; other writers speak of them as "complemental," reserving "supplemental" for full feeds given instead of breast-feeds. Cannot we get some agreement?

There are indications of hasty proof-reading throughout the book, but, as a whole, it is well written, and suitable for the purpose for which it is designed.

DETERMINATION OF HYDROGEN IONS.

THE third edition of Professor MANSFIELD CLARK'S well-known monograph on *The Determination of Hydrogen Ions*[4] has just appeared. As regards its quality it is sufficient to say that it maintains the high standard set by the previous editions. The author, in his preface, hints, however, that the book is in danger of being killed by its own success. The measurement of hydrogen-ion concentration has attained a remarkable and increasing popularity, a popularity that is very largely due to the work and writings of Mansfield Clark. In consequence the literature on the subject is expanding to unmanageable dimensions, and the author suggests that in a few years it will be as hopeless to recount all aspects of the utilization of the determination of hydrogen ions as it would be to note all the uses of thermometry. Again, the author expresses some dissatisfaction with his work on the grounds that the material has far outrun the range of the subject and the depth of treatment that can be encompassed. This dissatisfaction will not, however, be shared by his readers, for the writer expounds his difficult subject in a clear and readable style, and always succeeds in preventing the general principles from becoming lost in masses of technical detail. The main portion of the book treats of the general principles and technical details of the methods by means of which the hydrogen-ion concentration is determined. In a summary of thirty pages at the end the special applications of the method are mentioned. Then follows a bibliography of nearly a hundred pages, and the work concludes with an appendix containing tables of useful mathematical constants. Throughout the book all the most recent advances in technique are recorded, and the important ones are described in full working detail; this indicates that a vast amount of labour has been expended in the preparation of the new edition. The same point receives further confirmation from the fact that considerably more than half the references are to works published subsequent to the appearance of the last edition in 1924. Professor Mansfield Clark says in his preface: "Partly because the literature is what it is, the subject is not here presented as I conceive some genius will some day present it—with brilliant simplicity, and withal, rigidly." The readers of this book will, however, agree that in default of this hypothetical genius they are very thankful to possess the clear exposition given by the author. Moreover, if genius consists in a capacity for taking infinite pains, then Professor Mansfield Clark has earned the title very thoroughly.

We have also received a small book[5] written in German by Dr. GUNTHER LEHMANN, containing a careful and scientific study of the hydrogen ion from both the theoretical and practical standpoints. It can be commended, particularly to physicists, chemists, and bacteriologists. Numerous diagrams and illustrations of apparatus are provided, and the subject-matter is set out clearly, compensating to some extent for the absence of an index.

THE MEDICAL HISTORY OF CANADA.

DR. JOHN J. HEAGERTY of the Canadian Department of Health compels admiration not only for the amount of research involved in his two-volumed book *Four Centuries of Medical History in Canada, and a Sketch of the Medical History of Newfoundland*,[6] but also for the skill with which he has enlivened details that might otherwise have been dry as dust. As well as dealing with a lengthy period, this standard work covers a wide field of subjects, and, as Mr. A. G. Doughty remarks in a brief preface, the light it casts on the national history will interest the general reader. The early records of disease available for this history are fortunately very full, since the Jesuit missioners took meticulous notes and forwarded them to the headquarters of the Order in France, where they were carefully preserved. The subject-matter occupies eighty-four chapters, and the six parts into which the two volumes are divided deal with the epidemics of disease, the pioneer medical men, medicine and surgery, public health, the medical schools, and hospitals, the first of which was the Hôtel-Dieu at Quebec, opened by the French in 1639. The sketch of the medical history of Newfoundland, forming an appendix of about twenty pages, is a reproduction of an address given in 1925 by Dr. L. E. Keegan, president of the Newfoundland Medical Society.

Rather more than half of the first volume is devoted to the consideration of the following epidemic diseases: scurvy or mal de terre, small-pox, yellow fever or mal de Siam, plague, ship-fevers, mal de la Baie St. Paul, leprosy, cholera, and influenza. Scurvy was the first disease mentioned by the early explorers of the continent, and it attacked them as well as the Indians, who, however, had a remedy in the bark of a tree called "annedda"; interesting descriptions of its ravages are quoted from Jacques Cartier and Champlain. Small-pox appeared with the advent of white settlers and exterminated whole tribes of Indians, who suspected the Jesuits of causing it by witchcraft, and therefore tried to take their revenge. Inoculation was introduced about 1768, and vaccination as early as 1798 by John Clinch, a friend of Jenner. The Indians, who had the opportunity of this protection in 1806, did not take kindly to it, and indeed small-pox still exacts its toll from them. A specially interesting account is given of what was known as St. Paul's Bay disease, because it began in that locality about 1773; though presenting anomalous symptoms, it was regarded as syphilis, because of the curative effect of mercury. Before their contact with white settlers the Indians appear to have had few diseases, scurvy and eye affections caused by the irritation of the smoke in their dwellings being the commonest; whereas infections such as measles, scarlet fever, typhus and typhoid fever, diphtheria, venereal disease, and possibly tuberculosis were importations. The record of the pioneer medical men in the various provinces sometimes throws a curious light on their activities; thus Bonnerme, the first doctor to visit Quebec, narrowly escaped hanging for implication in a plot to poison Champlain, only to die the next year of scurvy. Michel Sarrazin (1659–1734), the most famous surgeon of his time in Canada, and a naturalist, described the beneficial effects on small-pox of an infusion of the roots of the pitcher-plant, called after him *Sarracenia canadensis*. The first medical journal in Canada—*Journal de médecine de Quebec*, published both in French and English—appeared in 1826 and survived for two years: the first medical society also started in the same city in 1826. Ether anaesthesia was first tried early in 1847 in Montreal, and chloroform in the following year in Quebec. The growth of public health is traced from the seventeenth century in

[6] *Four Centuries of Medical History in Canada, and a Sketch of the Medical History of Newfoundland.* By John J. Heagerty, M.D., D.P.H. With a preface by A. G. Doughty, C.M.G., F.R.S.C. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1928. (6½ × 9½; Vol. i, pp. xviii + 395; Vol. ii, pp. vii + 374; 38 illustrations. 50s. net the two volumes.)

detail, with accounts of quarantine arrangements, public health associations, and the development of vital statistics.

The sections on the medical schools and the hospitals, the sanatorium movement, and the care of the insane in the Dominion are mines of information, and an extensive bibliography and a good index complete the usefulness of this well-written work as a source of reference.

CLINICAL CHEMICAL PATHOLOGY.

A Handbook of Clinical Chemical Pathology,[7] by Dr. F. S. FOWWEATHER, is a short volume compiled for the special purpose of interpreting the work of the chemical pathologist to the clinician. Sir BERKELEY MOYNIHAN has contributed a foreword, and therein expounds very clearly the need for such a volume:

"This delegation of a part of the work involved in the application of laboratory tests from the clinician to a second person is perhaps unfortunate, but it is surely made inevitable by the growth of the subject. It has already been abused, and a system has to some extent grown up which has been rightly ridiculed as 'penny-in-the-slot diagnosis.' Here the clinician sends a specimen to the laboratory and expects to receive in return, not merely the result of the analysis, but also a brief diagnosis of his case. This abuse is due to the fact that the clinician has not sufficient knowledge to give him confidence to interpret for himself the results of chemical analysis and to incorporate them, along with the information he has gained from clinical examination of the patient, into a composite picture. The duty and the pleasurable task of making a diagnosis rests finally with the clinician, and never with the laboratory worker. It is with a desire to help the clinician to take advantage of laboratory methods in this way that the book has been written."

The author, in accordance with the purpose of this volume, has made no attempt to produce a handbook for laboratory workers, but has endeavoured to state concisely the nature and value of the more important methods used in clinical pathology. Among the subjects discussed are the acid-base balance, glycosuria, functional tests for the stomach, liver, and kidney, basal metabolism, calcium content of blood, and vitamins.

Pathological chemistry is a subject that has advanced very rapidly in recent years. The original literature on the subject is overwhelming in bulk, and most textbooks are so filled with technical details of laboratory methods as to be unreadable by others than specialists in the subject. These facts have made it extremely difficult for clinicians to keep in touch with the methods of pathological chemistry, which they nevertheless have had to employ. Dr. Fowweather's book should do much to remove the difficulty indicated, for it is written in a simple and easy style, and is so short that it can be read in an evening; but none the less it gives a clear and up-to-date account of the most important facts regarding the clinical value of pathological chemistry.

NOTES ON BOOKS.

THE issue of the *Medical Register*[8] for 1929 reveals the fact that the number of names added to it year by year continues to fall. The peak year of 1924, when there were 2,796 new entries, contrasts sharply with 1928, in which there was a decrease of 285 on the corresponding figure for 1927. The membership of the medical profession is still growing, however, and in 1928 amounted to 54,252. New registrations in England during 1928 numbered 859; in Scotland 404; in Ireland 217; and in the colonies and abroad 176. This total of 1,656 new entries compares with 1,941 in the preceding year. The number of names removed from the *Register* in 1928 was 1,038, as compared with 1,035 in 1927. Last year 845 names were removed on evidence of death, one due to cessation of practice, 188 because of failure to comply with the inquiries of the Registrar as to cessation of practice or change of address, while 4 were struck off under the disciplinary powers conferred by the Medical Act.

The *Dentists Register*[9] for 1929 contains 14,388 names, of which 6,824, or 47.43 per cent., are registered with medical, surgical, or dental qualifications. This compares with 6,788, or 46.57 per cent., so registered in the previous year, out of a total of 14,576 on the *Register*; the remainder in each case were registered under the provisions of the Dentists Acts of 1878 and 1921. Of the 264 new names added to the *Register* in 1928, 239 were registered with qualifications and 22 under the Dentists Act of 1921; this reveals a sharp decline from the numbers of the previous year—362 and 38 respectively. The number restored to the *Register* under the Acts of 1878 and 1921 was 251, and the number removed for this reason, or because of death, was 703. The useful local address list of previous years appears again, and indicates the dentists practising respectively in each postal district of London, each town or village of the United Kingdom, each town or country abroad, and in each of the Services.

The *Medical and Dental Students Register*,[10] issued by the General Medical Council, shows that the number of new medical students registered in 1928 was 1,363, which is 149 more than in the previous year. Scottish registrations numbered 577, an increase of 38. There were 545 English registrations—an increase of 42—and 241 Irish registrations, as compared with 172 in 1927. Dental students registered in 1928 numbered 256, an increase of 12 on the previous year.

A recent addition[11] to the "Notable British Trials" series deals with the case of Eugene Marie Chantrelle, who was executed in Edinburgh in 1878 for the murder of his wife by the administration of opium. Chantrelle in the first instance succeeded in creating the impression that death was due to poisoning caused by an undetected escape of gas in her bedroom. A *post-mortem* examination, however, showed no signs of coal-gas poisoning nor any evidence of the cause of death; analyses of vomit stains on bedding and on clothes worn by Madame Chantrelle, however, were found to contain considerable quantities of opium. This factor, coupled with evidence of the undoubted viciousness of the accused, and of the fact that he had a short time before insured his wife's life for a substantial sum—the policy taking effect only in the event of her death by accident—made his conviction certain. While medical evidence inevitably bulked largely in the proceedings at the trial, the matters dealt with are hardly of first-rate medico-legal importance to-day, and the main interest in the book centres round the character of Chantrelle, who appears to have been a villain of the type commonly depicted in old-fashioned melodrama—a man of good family and education, accomplished and intelligent, but ruthless, unscrupulous, debauched, and dishonourable.

In an attractively illustrated volume entitled *The Sack-'em-up Men: An Account of the Rise and Fall of the Modern Resurrectionists*,[12] Dr. JAMES MOORES BALL of St. Louis first summarizes the history of anatomy, thus touching one province of Dr. Charles Singer's authoritative writings, and then enters on his real subject, the activities of the body-snatchers, resurrection men, or sack-'em-up men who, a hundred and more years ago, provided the material for anatomical teaching in this country. He gives also some information about anatomical instruction in North America, including the "resurrection," as recently as 1878, at the Ohio Medical College, of John Scott Harrison, the son of one President and father of another President of the United States, the true story of which, he says, will not be published in our day. This monograph is dedicated to the Council and Fellows of the Royal College of Surgeons of Edinburgh, where the author collected illustrations and much of the material so well utilized here in these pages. The term "resurrection days" is applied to the period when the Irish, Scottish, and English teachers of anatomy were obliged by the existing state of the law to employ grave-robbers, who were not deprived of their occupation until the passing of the Anatomy Act in 1832, introduced by Henry Warburton. The familiar story of Burke and Hare a hundred years ago is accompanied by an account of the words "burking" and "burkism," and by many photographs, including a striking caricature of Robert Knox. The tragic story of the ruin of Knox is fully told; he was regarded by Lord Cockburn as one of the least culpable of the anatomists of his time; in fact, it was only an accident that saved Monro tertius from sharing his fate. Under the title of "respectable resurrectionists" some of the greatest names, such as Vesalius, John Hunter, Liston, and in America Valentine Mott, are included. For this well-written monograph the author has read widely, and with a light hand conveys much historical lore.

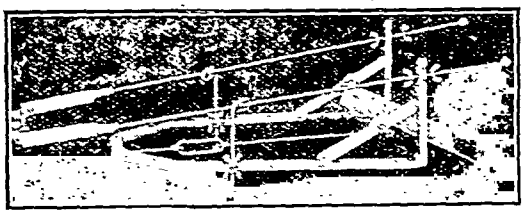
PREPARATIONS AND APPLIANCES.

IMPROVED SPLINT FOR TIBIA AND FIBULA FRACTURES.

DR. J. R. ATKINSON (Vancouver, British Columbia) writes:

My experience and the experience of others in the handling of fractures of the tibia and fibula has shown me the great difficulty, and in some cases the impossibility, of getting proper extension of the tibia and fibula and of holding them when correction is made. This led to the development of the splint shown and described herewith. After using it on every case of fracture of the lower limb which has come under my care during the past few years, and observing it in use by other doctors, I am able to state that results have been good.

The splint is for a fractured lower limb, and is designed to provide such support for the limb that the fractured ends

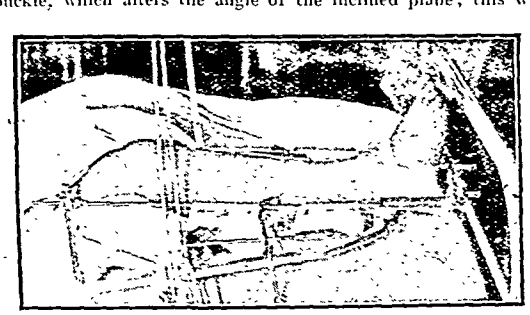


Splint for fractures of the lower limb.

may be drawn apart and readily adjusted, during which adjustment free access is afforded to the location of the fracture. When both bones of the lower leg are fractured the broken ends will, under the tension of the muscles, tend to overlap one another, and difficulty is experienced in applying the required tension to bring the fractured ends into their correct relative position, or when support is afforded from the crotch, without an exceedingly uncomfortable and painful pressure applied on this part, which is not adapted to receive such pressure.

In this splint the required resistance for the tension applied to draw the fractured ends of a broken leg to their proper position in relation to one another is imposed on the underside or back of the thigh, adjacent the knee-joint, the axis of the thigh being angled to that of the leg to provide a suitable resistance. The splint frame, by which the tension is imposed on the leg and the resistance of that tension distributed, is so designed to afford free access to the leg at the location of the fracture for an inspection of it generally, or by x rays, and for manipulation, or for attending to any open wound on any part of the leg or foot. The uprights may be adjusted to impose the required torsion or twist on the limb to bring the fractured ends together.

It will be noted that the angle at which the leg is held in relation to that of the thigh may be adjusted by the turnbuckle, which alters the angle of the inclined plane; this will



The splint in use; the thigh and ankle bandages are quite loose.

also alter the anterior or posterior alignment of the bones. Such parts of the splint as are directly connected to the limb are adjustable so that it may be adaptable to variation in the size of the limb it may be required to be used on.

The splint is not only convenient for the operator, as it offers ample facilities for inspection and manipulation of the fractured limb, but it is also comfortable for the patient. As the splint firmly attaches the injured leg to the thigh, and to no other part, the patient has freedom of movement, and can assume the position which is most comfortable; it permits the patient to use a wheel-chair, and to assume a sitting posture in bed if desired. As a first-aid splint it is convenient and safe, as anyone in a factory or camp can apply it temporarily (over boot and clothing) to a fellow worker to prevent further injury while the patient is being moved to a hospital, thus eliminating serious complications which often arise after an accident. The limb cannot slip or get out of place, freedom of motion is allowed the rest of the body, and the limb can be placed under the fluoroscope and the fractured ends be seen as they are being pulled into their correct position. After setting, the splint is locked, and the fractured leg may be comfortably supported from the bed on a Balkan frame or other swing. Radiographs can be taken as often as required while the limb is in the splint. Physiotherapy, careful massage, and stimulation with a faradic current or lamp can be practised.

The frame is made of burnished aluminium, and the complete splint weighs about 5½ lb. It has ample strength, and is simple and positive in operation. The advantages claimed are: (1) prevention of shortening and deformity; (2) lessens danger of knee- and ankle-joint stiffness; (3) lessens danger of atrophy of leg muscles; (4) time required for recovery is materially shortened; (5) comfort for the patient; (6) convenience and assurance for the operator.

MILK PREPARATIONS.

We have received a series of samples from the West Surrey Central Dairy Company. During recent years knowledge of infant feeding has advanced rapidly, and this company are putting on the market a number of substances which have been prepared in accordance with the results of recent research on infant nutrition. These preparations should prove a great convenience to the medical profession, for it is always difficult, and often impossible, to prepare privately many of the special mixtures for infant feeding that have been proved to be of benefit in institutions.

Cow and Gate Milk Food is a dried milk manufactured from pure English milk. It is made in two strengths—namely, half cream milk and full cream milk. The makers point out that dried milk has a special value for infant feeding in tropical and sub-tropical countries. They quote evidence that the milk available for purchase in India is very frequently adulterated and contaminated, and that the use of dried milk reduces the risk of dysentery and diarrhoea from fly infection.

Brestol.—The makers argue that "Hitherto, when it has been found necessary to apply modification in infant feeding, the physician has had to resort to dairy creams of uncertain composition, or to emulsions of an unsatisfactory character. Dairy cream, with its uncertain fat, and protein, and preservative content, with its doubtful bacteriological (including tubercle) content, and with its questionable vitamin activity, has also the disadvantage of bad keeping qualities; whilst in most emulsions full cognizance has not been taken of the necessity for supplying to the infant a cream possessing properties and characteristics identical with those of healthy breast milk." They have therefore prepared an emulsion of fats which has a saponification number and iodine number identical with those of human milk. Fat-soluble vitamins and orange juice have been added. The manufacturers claim that brestol is a product "which is easily and accurately prescribed, readily digested and assimilated, and which will be found invaluable in all cases of infant feeding and diet rectification."

Lacidac is a preparation of dried milk to which lactic acid has been added so that one pint of milk will contain one fluid drachm of lactic acid *B.P.* The preparation is made in two strengths—namely, separated (1 per cent. fat) and half cream (16 per cent. fat). This preparation is made in accordance with the researches of Marriott (*Journ. Amer. Med. Assoc.*, 81, 2007; 89, 862), who found that marasmic children frequently suffered from deficient gastric acidity, and that the administration of lactic acid milk reduced the mortality of such infants from 78 per cent. to 26 per cent.

Haemolac is dried cow's milk to which a small quantity of iron has been added (0.55 per cent. iron and ammonium citrate in dried milk). Cow's milk only contains about one-third the iron content of human milk, and Mackay (*Arch. of Dis. in Childhood*, 3, 117, 1928) showed that whilst the normal haemoglobin percentage in the blood of infants from 4 months upwards was at least 80 per cent. of the adult normal, yet 25 per cent. of artificially fed infants fell below this standard. She found that administration of a medicated milk of the same formula as haemolac produced a striking benefit. The iron content of haemolac, which is about 200 mg. Fe_2O_3 per 100 grams, is far higher than that of human milk, which is 4 mg. Fe_2O_3 per 100 grams of dry substance, and the iron causes the stools of the infants to turn black. *Haemolac* is recommended for premature infants, babies under weight at birth, and anaemic babies. It seems to have been prepared on a basis of sound physiological and clinical evidence. In view of the great difference between the iron content of haemolac and of normal milk, it would, however, be interesting to know whether equally good results could not be obtained with a quantity of iron somewhat nearer the normal content.

Lacquin is dried milk to which quinine has been added so that half a pint of prepared milk (breakfast cup) contains 2½ grains of quinine. The milk is also flavoured with coffee. This preparation is recommended as a method by which prophylactic doses of quinine can be taken by children or adults in a palatable form. Moreover, it provides an easy method of giving infants quinine in doses approaching the usual curative dose. The makers state, however, that children with malaria require relatively large doses of quinine, and that therefore additional quinine would be needed for curative treatment.

"EXANTHEMATIDES."

SECOND LETTSOMIAN LECTURE BY DR. H. W. BARBER.

THE second Lettsomian Lecture[1] by Dr. H. WORDSWORTH BARBER was delivered to the Medical Society of London on March 6th. Dr. Barber's general subject is dermatology in relation to other branches of medicine, and on this occasion he dealt with the nature and significance of a group of eruptions provoked by micro-organisms or toxins reaching the skin by way of the blood stream, to which eruptions he gave the generic name "exanthematides." Under this term were included the syphilides, tuberculides, and trichophytides, together with certain eruptions, some of which might be associated with rheumatic diseases, and for which the term "streptococcides" was suggested.

Syphilis, Tuberculosis, and Rheumatic Fever Compared.

Syphilis and tuberculosis, said the lecturer, were outstanding among diseases, if the specific fevers were excluded, for their ubiquity, their serious nature, their chronicity, and the amount of information collected concerning them, and they had dominated medical thought and research for generations; they still dominated dermatological thought and research over the greater part of the world, for syphilis and tuberculosis belonged in great part to the domain of dermatology. Rheumatic diseases also had cutaneous manifestations which were so closely akin to certain syphilitic and tuberculous eruptions in their mechanism of production and significance that one was able to draw from them deductions of the highest importance. The evidence that rheumatic fever was allergic in nature, and that the streptococcal group of organisms was responsible, seemed to the lecturer to be overwhelming; he had yet to hear any argument to the contrary that would bear examination. In all three diseases—syphilis, tuberculosis, and rheumatic fever—there was usually an initial lesion, and in all three there was a decided tendency to relapse, which seemed to be due to the breakdown of a partial immunity. In both tuberculosis and rheumatic fever the presence of lesions in the walls of the serous cavities or joints was accompanied by the outpouring of a sero-fibrous exudate. It was true that differences could be found between the three diseases, and in these differences consisted the peculiar features of the respective maladies. He was led, therefore, to submit a comparison between certain cutaneous manifestations of tuberculosis and syphilis, together with those of the severer forms of ringworm infection, on the one hand, and those of rheumatic or streptococcal infection on the other. All these eruptions might be conveniently classed together as "exanthematides."

The Syphilides, Tuberculides, and Trichophytides.
